1 Introduction

This document describes the STELLA programming language. STELLA stands for Strongly-TypEd, Lisp-like LAnguage. It is an object-oriented language that strongly supports symbolic programming tasks. We developed it, since none of the currently "healthy" languages such as C++ or Java adequately support symbolic programming. While Common-Lisp would probably still be today's language of choice for many symbolic programming applications, its dwindling vendor support and user base make it more and more difficult to justify its use.

When we started the development of the PowerLoom knowledge representation system in 1995 we were faced with exactly this problem. PowerLoom had to be delivered in C++, but it was simply incoceivable to write such a large symbolic programming application directly in C++. The solution was to invent a new programming language we called STELLA and write PowerLoom in STELLA instead.

STELLA is a strongly typed, object-oriented, Lisp-like language specifically geared to support artificial intelligence applications. STELLA preserves those features of Common Lisp deemed essential for symbolic programming such as built-in support for dynamic data structures, heterogeneous collections, first-class symbols, powerful iteration constructs, name spaces, an object-oriented type system with a simple meta-object protocol, exception handling, language extensibility through macros and automatic memory management. Maybe the biggest difference between STELLA and Common Lisp is that STELLA is strongly typed. All externally visible interfaces such as slots, function parameters and return values, etc. have to be explicitly typed. Internal objects such as local variables, however, are mostly typed implicitly supported by type inference. This in conjunction with a powerful type coercion mechanism significantly reduces the number of explicit type information that needs to be supplied by the programmer compared to languages such as C++ or Java.

STELLA programs are first translated into a target language such as Common Lisp, C++ or Java, and then compiled with the native target language compiler to generate executable code. The language constructs of STELLA are restricted to those that can be translated fairly directly into native constructs of the intended target languages. This allows STELLA to be translated into efficient, conventional and readable Lisp, C++ and Java code. The resulting native code can be understood and to some extent even maintained by programmers who don't know STELLA, and it can easily be interfaced with other programs not written in STELLA.

As of Fall 2000, we have programmed approximately 100,000 lines of STELLA code about 50% for the STELLA kernel itself and the other 50% for the PowerLoom knowledge representation system and related systems. Our subjective experience has been that it is only slightly more difficult to write and debug a STELLA program than a Lisp program, and that the inconvenience of having to supply some type information is much outweighed by the benefits such as catching many errors during compile time instead of at run time.

The biggest benefit, however, seems to be that we can still leverage all the incremental code development benefits of Lisp, since we use the Common Lisp-based version of STELLA for prototyping. This allows us to incrementally define and redefine functions, methods and classes and to inspect, debug and fix incorrect code on the fly. Even the most sophisticated C++ or Java IDE's don't yet seem to support this fully incremental development style, i.e.,

a change in a class (every change in Java is a change to a class) still requires recompilation and restart of the application. But it is the restart that can be the most time consuming if one debugs a complex application that takes a significant time to reach a certain state!

Once a STELLA program has matured, it can be translated into C++ or Java to gain extra efficiency, to deliver it as a stand-alone application, or to link it with other programs.

1.1 Credits and History

Bob MacGregor invented STELLA in 1995 to implement the PowerLoom knowledge representation system. He wrote most of the first Lisp-based kernel system of STELLA and still occasionally writes extensions or provides fixes. Today he is primarily a STELLA user writing his own applications.

Hans Chalupsky completed the first full STELLA bootstrap (STELLA translating itself) in Spring 1996, and then went on to deal with all the changes necessary to handle the many C++ and Java idiosyncrasies that were discovered when the first versions of these translators came online. He is currently one of the principal maintainers of STELLA supporting the STELLA code analyzer and the Lisp and C++ translators.

Eric Melz wrote the first version of the C++ translator under very trying circumstances (i.e., at a stage where the STELLA language changed under him on a daily basis). He got the first C++ version of STELLA running in the Fall of 1996.

Tom Russ wrote the Java translator and got the first Java version of STELLA running in Spring 1999. He is currently one of the principal maintainers of STELLA supporting the STELLA code analyzer and the Lisp and Java translators. He is also still active writing occasional extensions such as the STELLA XML parser.

2 Installation

2.1 System Requirements

To install and use STELLA you'll approximately need the following amounts of disk space:

- 8 MB for the tar-red or zip-ped archive file
- 35 MB for the untarred sources, tanslations, compiled Java files and documentation
- 8 MB to compile a Lisp version
- 11 MB to compile the C++ version (without -g)
- 3 MB to compile the Java version (already included)

This means that you will need approximately 55 MB to work with one Lisp, one C++ and one Java version of STELLA in parallel. If you also want to experiment with the Lisp translation variant that uses structures instead of CLOS instances to implement STELLA objects, then you will need an extra 8 MB to compile that.

The full STELLA development tree is quite large, since for every STELLA source file there are three to four translated versions and as many compiled versions thereof. The actual STELLA libraries that you have to ship with an application, however, are quite small. For example, the Java jar file stella.jar is only about 1.3 MB in size. The dynamic C++ library libstella.so compiled on a Linux platform is about 4 MB. Additionally, if you don't need all the different translations of STELLA, you can delete some of the versions to keep your development tree smaller (See Section 2.7 [Removing Unneeded Files], page 6).

To run the Lisp version of STELLA you need an ANSI Common-Lisp (or at least one that supports CLOS and logical pathnames). We have successfully tested STELLA with Allegro-CL 4.2, 4.3, 5.0, 6.0 and 7.0, Macintosh MCL 3.0, 4.0 and 5.1, OpenMCL 1.0, SBCL 0.9.4, CMUCL 19c, LispWorks 4.4.6, CLisp 2.37, Lucid CL 4.1 (plus the necessary ANSI extensions and Mark Kantrowitz's logical pathnames implementation) and various others. Our main development platform is Allegro CL running under Sun Solaris and Linux, so, the closer your environment is to ours, the higher are the chances that everything will work right out of the box. Lisp development under Windows should also be no problem.

To run the C++ version of STELLA you need a C++ compiler such as g++ that supports templates and exception handling. We have successfully compiled and run STELLA with g++ 3.2 and later under Linux Redhat 8.0 & 9.0, SunOS and MacOS X, and with CygWin 5.0 and MinGW 5.0 under Windows 2000 and XP. Both CygWin and MinGW provide a GNU Unix environment, but MinGW can generate Windows executables that are fully standalone. We've also managed to compile STELLA under MS Visual C++, however, we never got the Boehm garbage collector to work. The GC claims to be very portable, so this should be solvable for somebody with good knowledge of MS Visual C++.

For the Java version you will need Java JDK 1.2 or later. To get reasonable performance, you should use J2SDK 1.4 or 1.5. We've run the Java version of STELLA on a variety of platforms without any problems.

Any one of the Lisp, C++ or Java implementations of STELLA can be used to develop your own STELLA code and translate it into all three languages, but the most convenient development environment is the one based on Lisp. If you use the C++ or Java version, translating and using your own STELLA macros is possible but not yet very well supported.

2.2 Unpacking the Sources

Uncompress and untar the file stella-X.Y.Z.tar.gz (or unzip the file stella-X.Y.Z.zip) in the parent directory of where you want to install STELLA ('X.Y.Z' are place holders for the actual version numbers). This will create the STELLA tree in the directory stella-X.Y.Z/. All pathnames mentioned below will be relative to that directory which we will usually refer to as the "STELLA directory".

2.3 Lisp Installation

To install the Lisp version startup Lisp and load the file load-stella.lisp with:

```
(CL:load "load-stella.lisp")
```

The first time around this will compile all Lisp-translated STELLA files before they are loaded. During subsequent sessions the compiled files will be loaded right away.

If you want to use the version that uses Lisp structs instead of CLOS objects to implement STELLA objects do the following:

```
(CL:setq cl-user::*load-cl-struct-stella?* CL:t)
(CL:load "load-stella.lisp")
```

Alternatively, you can edit the initial value of the variable *load-cl-struct-stella?* in the file load-stella.lisp. Using structs instead of CLOS objects greatly improves slot access speed, however, it may cause problems with incremental re-definition of STELLA classes. It is therefore recommended to only use this for systems that are in or near the production stage.

Once all the files are loaded, you should see a message like this:

```
Initializing STELLA...
STELLA 3.4.0 loaded.
Type '(in-package "STELLA")' to execute STELLA commands.
USER(2):
```

To reduce startup time, you might want to create a Lisp image that has all of STELLA preloaded.

```
Now type
```

```
(in-package "STELLA")
```

to enter the STELLA Lisp package where all the STELLA code resides.

IMPORTANT: All unqualified Lisp symbols in this document are assumed to be in the STELLA Lisp package. Moreover, the STELLA package does NOT inherit anything from the COMMON-LISP package (see the file sources/stella/cl-lib/cl-setup.lisp for the few exceptions), hence, you have to explicitly qualify every Lisp symbol you want to use with CL:. For example, to get the result of the previous evaluation you have to type CL:* instead of *.

2.4 C++ Installation

To compile the C++ version of STELLA change to the native C++ directory and run make:

```
% cd native/cpp/stella
% make
```

This will compile all STELLA files, the garbage collector and generate a static or dynamic libstella library file in the directory native/cpp/lib which can later be linked with your own C++-translated STELLA (or other) code. To test whether the compilation was successful you can run STELLA from the top-level STELLA directory using the stella script (or stella.bat under a Windows command prompt):

```
% stella c++
Running C++ version of STELLA...
Welcome to STELLA 3.4.0
Running kernel startup code...
Initializing symbol tables...
Initializing quoted constants...
Initializing global variables...
Creating class objects...
Finalizing classes...
Creating method objects...
Finalizing methods...
Running non-phased startup code...
Starting up translators...
Bye!
```

This will simply run various STELLA startup code and exit. See Section 4.1.2 [Hello World in C++], page 14, to see how you can use the STELLA C++ executable to translate STELLA code. The c++ argument tells the script to run the C++ version of STELLA. If the argument is omitted and the C++ version is installed, it will be run automatically. Otherwise, the Java version will be run.

2.5 Java Installation

Nothing needs to be done to install the Java version. Since Java class files are platform independent, they are already shipped with the STELLA distribution and can be found in the directory native/java and its subdirectories. Additionally, they have been collected into the file native/java/lib/stella.jar. To try out the Java version of STELLA run the stella script in the STELLA directory:

```
% stella java
Running Java version of STELLA...
Welcome to STELLA 3.4.0
Running kernel startup code...
Initializing symbol tables...
Initializing quoted constants...
Initializing global variables...
Creating class objects...
Finalizing classes...
Creating method objects...
Finalizing methods...
Running non-phased startup code...
Starting up translators...
Bye!
```

Similar to the C++ executable, this will simply run various STELLA startup code and exit. See Section 4.1.3 [Hello World in Java], page 16, to see how you can use the STELLA Java executable to translate STELLA code.

2.6 X/Emacs Setup

STELLA development is very similar to Lisp development, and it is best done in an X/Emacs-based Lisp development environment such as the Allegro-CL Emacs interface plus Allegro Composer, or ILISP. If you do use X/Emacs with the Allegro CL interface, add the following to your .emacs or .xemacs/init.el file:

```
(setq auto-mode-alist
          (cons '("\\.ste$" . fi:common-lisp-mode) auto-mode-alist))
```

If you are using the Allegro CL interface, you might want to install the file emacs/fi-stella.el, since it sets up proper indentation for STELLA code and makes looking up STELLA definitions via the C-c. or M-. commands work better. Look at the file emacs/fi-stella.el for specific installation instructions.

2.7 Removing Unneeded Files

To save disk space you can remove files that you don't need. For example, if you are not interested in the C++ version of STELLA, you can delete the directory native/cpp. Similarly, you can remove native/java to eliminate all Java-related files. You could do the same thing for the Lisp directory native/lisp, but (in our opinion) that would make it less convenient for you to develop new STELLA code. Finally, if you don't need any of the STELLA sources, you can delete the directory sources/stella. If you don't need local copies of the STELLA documentation, you can delete parts or all of the sources/stella/doc directory.

3 The STELLA Language

3.1 Language Overview

STELLA is a strongly typed, object-oriented, Lisp-like language. STELLA programs are first translated into either Common Lisp, C++, or Java, and then compiled with any conventional compiler for the chosen target language to generate executable code. Over 95% of the STELLA system is written in STELLA itself, the rest is written in target-language-specific native code.

The design of STELLA borrows from a variety of programming languages, most prominently from Common Lisp, and to a lesser degree from other object-oriented languages such as Eiffel, Sather, and Dylan. Since STELLA has to be translatable into C++ and Java, various restrictions of these languages also influenced its design.

In the following, we assume that the reader is familiar with basic Common Lisp concepts, and has at least some familiarity with C++ or Java. Let us start with a cursory overview of STELLA's main features:

Syntax: STELLA uses a parenthesized, uniform expression syntax similar to Lisp. Most definitional constructs and control structures are similar to their Common Lisp analogues with variations to support types.

Type system: STELLA is strongly typed and supports efficient static compilation similar to C++. Types are required for the arguments and return values of functions and methods, for global variables, and for slot definitions. Local, lexically scoped variables can be typed implicitly by relying on type inference.

Object system: Types are organized into a single inheritance class hierarchy. Restricted multiple inheritance is allowed via mixin classes. Dynamic method dispatch is based on the runtime type of the first argument (similar to C++ and Java). Slots can be static (native) or dynamic. Dynamic slots can be defined at runtime and do not occupy any space until they are filled. Slots can have both initial and default values, and demons can be triggered by slot accesses. A meta-object protocol allows the control of object creation, initialization, termination, and destruction.

Control structure: Functions and methods are distinguished. They can have multiple (zero or more) return values and a variable number of arguments. Lisp-style macros are supported to facilitate syntax extensions. Expressions and statements are distinguished. Local variables are lexically scoped, but dynamically scoped variables (specials) are also supported. STELLA has an elegant, uniform, and efficient iteration mechanism plus a built-in protocol for iterators. An exception mechanism can be used for error handling and non-local exits.

Symbolic programming: Symbols are first-class objects, and extensive support for dynamic datatypes such as cons-trees, lists, sets, association lists, hash tables, extensible vectors, etc., is available. A backquote mechanism facilitates macro writing and code generation. Interpreted function call, method call, slot access, and object creation is supported, and a restricted evaluator is also available.

Name spaces: Functions, methods, variables, and classes occupy separate name spaces (i.e., the same name can be used for a function and a class). A hierarchical module system compartmentalizes symbol tables and supports large-scale programming.

Memory management: STELLA relies on automatic memory management via a garbage collector. For Lisp and Java the native garbage collector is used. For the C++ version of STELLA we use the Boehm- Weiser conservative garbage collector with good results. Various built-in support for explicit memory management is also available.

The Common Lisp features most prominently absent from STELLA are anonymous functions via lambda abstraction, lexical closures, multi-methods, full-fledged eval (a restricted evaluator is available), optional and keyword arguments, and a modifiable readtable. STELLA does also not allow dynamic re/definition of functions and classes, even though the Lisp-based development environment provides this facility (similar to Dylan). The main influences of C++ and Java onto STELLA are the strong typing, limited multiple inheritance, first-argument polymorphism, and the distinction between statements and expressions.

3.2 Basic Data Types (tbw)

To be written.

3.3 Control Structure (tbc)

To be completed.

3.3.1 Conditionals

STELLA conditionals are very similar to those found in Common-Lisp. The main difference is that most STELLA conditionals are statements and therefore do not return a value. For this reason, a C++-style choose directive has been added to the language to allow value conditionalization based on a boolean expression.

if condition then-statement else-statement

[Statement]

Evaluate the boolean expression condition. If the result is true execute thenstatement, otherwise, execute else-statement. Note that unlike the Common-Lisp version of if the else-statement is not optional in STELLA. Example:

```
(if (> x y)
     (print "x is greater than y" EOL)
     (print "x is less than or equal to y" EOL))
```

when condition statement...

[Statement]

Evaluate the boolean expression *condition*. Only if the result is true execute the *statement*'s in the body. Example:

```
(when (symbol? x)
  (print "x is a symbol, ")
  (print "its name is " (symbol-name (cast x SYMBOL)) EOL))
```

unless condition statement...

|Statement|

Evaluate the boolean expression condition. Only if the result is false execute the statement's in the body. Therefore, (unless test ...) is equivalent to (when (not test) ...). Example:

```
(unless (symbol? x)
  (print "x is not a symbol, ")
  (print "hence, its name is unknown" EOL))
```

cond clause... [Statement]

cond is a conditional with an arbitrary number of conditions each represented by a clause. Each cond clause has to be of the following form:

```
(condition statement...)
```

The first clause whose condition evaluates to true will be selected and its statement's will be executed. Each clause can have 0 or more statements. The special condition otherwise always evaluates to true and can be used for the catch-all case. Example:

choose condition true-expression false-expression

[Expression]

Evaluate the boolean expression condition. If the result is true return the value of true-expression, otherwise, return the value of false-expression. STELLA computes the most specific common supertype of true-expression and false-expression and uses that as the type returned by the choose expression. If no such type exists, a translation error will be signaled. Example:

```
(setq face (choose happy? :smile :frown))
```

case expression clause...

[Statement]

Each case clause has to be of one of the following forms:

```
(key statement...)
((key...) statement...)
```

case selects the first clause whose key (or one of the listed key's) matches the result of expression and executes the clause's statement's. Each case key has to be a constant such as a number, character, string, symbol, keyword or surrogate. Keys are compared with eql? (or string-eql? for strings). All keys in a case statement have to be of the same type. The special key otherwise can be used to catch everything. It is a run-time error if no clause with a matching key exists. Therefore, a STELLA case without an otherwise clause corresponds to a Common Lisp ecase. An empty otherwise clause can always be specified via (otherwise NULL). Example:

```
(case car-make
  ("Yugo"
    (setq price :cheap))
  ("VW"
    (setq price :medium))
  (("Ferrari" "Rolls Royce")
    (setq price :expensive))
  (otherwise
    (setq price :unknown)))
```

typecase expression clause...

[Statement]

Each typecase clause has to be of one of the following forms:

```
(type statement...)
```

```
((type...) statement...)
```

typecase selects the first clause whose type (or one of the listed type's) equals or is a supertype of the run-time type of the result of expression and then executes the clause's statement's. Therefore, typecase can be used to implement a type dispatch for cases where the run-time type of an expression can be different from the static type known at translation time. Currently, the static type of expression is required to be a subtype of OBJECT.

Each type expression has to be a symbol describing a simple type (i.e., parametric or anchored types are not allowed). Similar to case, the special key otherwise can be used to catch everything. It is a run-time error if no clause with a matching type exists. Therefore, a STELLA typecase without an otherwise clause corresponds to a Common Lisp etypecase. An empty otherwise clause can always be specified via (otherwise NULL). typecase does allow the value of expression to be undefined, in which case the otherwise clause is selected. Example:

```
(typecase (first list)
  (CONS
    (print "it is a cons"))
  ((SYMBOL KEYWORD)
    (print "it is a symbol"))
  (STANDARD-OBJECT
    (print "it is a regular object"))
  (otherwise NULL))
```

Note that in the example above it is important to list STANDARD-OBJECT after SYMBOL and CONS, since it subsumes the preceding types. Otherwise, it would always shadow the clauses with the more specific types.

The semantics of typecase is slightly extended for the case where expression is a local variable. In that case each reference to the variable within a typecase clause is automatically casted to the appropriate narrower type. For example, in the code snippet below method calls such as first or slot accesses such as symbol-name are translated correctly without needing to explicitly downcast x which is assumed to be of type OBJECT:

```
(typecase x
  (CONS
   (print "it is a cons with value " (first x)))
  ((SYMBOL KEYWORD)
   (print "it is a symbol with name " (symbol-name x)))
  (STANDARD-OBJECT
   (print "it is a regular object"))
  (otherwise NULL))
```

Since the typecase expression has to be a subtype of OBJECT, a typecase cannot be used to test against literal types such as STRING or INTEGER. If such type names are encountered as keys in a typecase, they are automatically converted to their wrapped version, e.g., STRING-WRAPPER, INTEGER-WRAPPER, etc.

3.4 Functions (tbw)

To be written.

3.5 Classes (tbw)

To be written.

3.6 Methods (tbw)

To be written.

3.7 Macros (tbw)

To be written.

3.8 Modules (tbw)

To be written.

4 Programming in STELLA

4.1 Hello World in STELLA

Included with the STELLA distribution is a simple Hello World application that shows you how to organize your own STELLA code and build a working STELLA application. The sources for the Hello World system consist of the following files:

```
sources/systems/hello-world-system.ste
sources/hello-world/file-a.ste
sources/hello-world/file-b.ste
```

STELLA organizes code modules with a simple system facility. Translation always operates on a complete system, so you always need to create a system definition for the STELLA files comprising your application (somewhat similar to what you would put in a Unix Makefile).

For the Hello World system the system definition already exists and resides in the file sources/systems/hello-world-system.ste. By default, STELLA looks in the directory sources/systems to find the definition of a particular system. hello-world-system.ste defines two things:

(1) The HELLO-WORLD module which defines a namespace for all objects in the Hello World systems. STELLA modules are mapped onto corresponding native namespace constructs, i.e., Lisp packages, C++ namespaces or Java packages. The exact mapping for each language can be defined via the keyword options :lisp-package, :cpp-package and :java-package in the module definition, for example:

```
(defmodule "HELLO-WORLD"
  :lisp-package "STELLA"
  :cpp-package "hello_world"
  :java-package "edu.isi.hello_world"
  :uses ("STELLA"))
```

The :uses directive tells STELLA from what other modules this one inherits.

(2) The actual system definitions defining what source files comprise the system, and what parent systems this one depends on, plus a variety of other options:

4.1.1 Hello World in Lisp

To generate a Lisp translation of Hello World you can use either the Lisp, C++ or Java version of STELLA. Before you can translate you have to make sure the following native directories exist:

```
native/lisp/hello-world/
```

```
bin/acl7.0/hello-world/
```

The directory native/lisp/hello-world/ will hold the Lisp translations of the corresponding STELLA source files. The directory bin/acl7.0/hello-world/ will hold the compiled Lisp files if you are using Allegro CL 7.0. If you are using a different Lisp, one of the other binary directories as defined in the top-level file translations.lisp will be used. The directory bin/lisp/hello-world/ will be used as a fall-back if your version of Lisp is not yet handled in translations.lisp.

If you create your own system, you will need to create those directories by hand (future versions of STELLA might do that automatically). For the Hello World system these directories already exist.

To generate a Lisp translation of Hello World using Lisp startup a Lisp version of STELLA (see Section 2.3 [Lisp Installation], page 4). The following idiom will then translate the system into Lisp and also Lisp-compile and load it. The first argument to make-system is the name of the system, and the second argument indicates into what language it should be translated:

```
STELLA(3): (make-system "hello-world" :common-lisp)
  Processing '/tmp/stella-3.1.0/sources/hello-world/file-a.ste':
  *** Pass 1, generating objects...
  Processing '/tmp/stella-3.1.0/sources/hello-world/file-b.ste':
  *** Pass 1, generating objects...
     ;;; Writing fasl file
        /tmp/stella-3.1.0/native/lisp/bin/acl7.0/hello-world/startup-system.fasl
  ;;; Fasl write complete
  ; Fast loading
       /tmp/stella-3.1.0/native/lisp/bin/acl7.0/hello-world/startup-system.fasl
  CL:T
  STELLA(4):
After the system is loaded you can call its main function:
  STELLA(10): (main)
  Hello World A
  Hello World B
  bye
  ()
  STELLA(11):
```

Using main in the Lisp version will not always make sense, since you can call any function directly at the Lisp top level, but both C++ and Java always need a main function as a top-level entry point.

While this would be somewhat unusual, you could also generate the Lisp translation using the C++ or Java version of STELLA. The easiest way to do that is to run the stella script in the STELLA directory like this:

```
% ./stella -e '(make-system "hello-world" :common-lisp)'
Running C++ version of STELLA...
Welcome to STELLA 3.4.0
Processing 'sources/hello-world/file-a.ste':
```

The -e command line option is used to evaluate an evaluable STELLA command. Conveniently, make-system is such a command, so you can supply a make-system form to the C++ or Java version of STELLA just as you would do in Lisp. Note the extra quotes around the expression to protect the characters from interpretation by the Unix shell.

To compile and load the translated Lisp files into Lisp you then have to startup a Lisp version of STELLA and call make-system again which now will only compile and load the necessary files, since the translations have already been generated in the previous step.

4.1.2 Hello World in C++

To generate a C++ translation of Hello World you can use either the Lisp, C++ or Java version of STELLA. Before you can translate you have to make sure the following native directory exists:

```
native/cpp/hello-world/
```

The directory native/cpp/hello-world/ will hold the C++ translations of the corresponding STELLA source files. If you create your own system, you will need to create this directory by hand (future versions of STELLA might do that automatically). For the Hello World system the directory already exist.

To generate a C++ translation of Hello World using Lisp startup a Lisp version of STELLA (see Section 2.3 [Lisp Installation], page 4). The following idiom will then translate the system into C++. The first argument to make-system is the name of the system, and the second argument indicates into what language it should be translated:

Alternatively, you can generate the translation using the C++ or Java version of STELLA. The easiest way to do that is to run the stella script in the STELLA directory like this:

```
% ./stella -e '(make-system "hello-world" :cpp)'
```

```
Running C++ version of STELLA...

Welcome to STELLA 3.4.0

Processing 'sources/hello-world/file-a.ste':

*** Pass 1, generating objects...

Processing 'sources/hello-world/file-b.ste':

*** Pass 1, generating objects...

Writing 'native/cpp/hello-world/file-b.hh'...

Writing 'native/cpp/hello-world/file-b.cc'...

Translating 'sources/hello-world/startup-system.ste'.

Writing 'native/cpp/hello-world/startup-system.hh'...

Writing 'native/cpp/hello-world/startup-system.cc'...
```

The -e command line option is used to evaluate an evaluable STELLA command. Conveniently, make-system is such a command, so you can supply a make-system form to the C++ or Java version of STELLA just as you would do in Lisp. Note the extra quotes around the expression to protect the characters from interpretation by the Unix shell.

Different from Lisp, neither of the above idioms will compile and load the generated C++ code. Instead you have to use the Unix make facility to compile and link the C++ sources. First change into the native hello-world directory and then call make (important: the generated Makefiles currently require the GNU version of make):

The first time around this will also compile the C++ version of STELLA and the C++ garbage collector and create a STELLA library file. Future builds of the Hello World and other systems will use the STELLA library file directly. To run the Hello World system simply run the hello-world executable that was built in the previous step:

```
% ./hello-world
Hello World A
Hello World B
bye
```

4.1.3 Hello World in Java

To generate a Java translation of Hello World you can use either the Lisp, C++ or Java version of STELLA. Before you can translate you have to make sure the following native directory exists:

```
native/java/edu/isi/hello-world/
```

The directory native/java/edu/isi/hello-world/ will hold the Java translations of the corresponding STELLA source files. If you create your own system, you will need to create this directory by hand (future versions of STELLA might do that automatically). For the Hello World system the directory already exist.

Note that following Java convention we use the package edu.isi.hello_world to hold the Hello World system. This was specified via the :java-package option in the definition of the HELLO-WORLD module. Also note that we use hello_world instead of hello-world as the package name, since a dash cannot legally appear as part of a Java identifier.

To generate a Java translation of Hello World using Lisp startup a Lisp version of STELLA (see Section 2.3 [Lisp Installation], page 4). The following idiom will then translate the system into Java. The first argument to make-system is the name of the system, and the second argument indicates into what language it should be translated:

Alternatively, you can generate the translation using the C++ or Java version of STELLA. The easiest way to do that is to run the stella script in the STELLA directory like this:

The -e command line option is used to evaluate an evaluable STELLA command. Conveniently, make-system is such a command, so you can supply a make-system form to the C++ or Java version of STELLA just as you would do in Lisp. Note the extra quotes around the expression to protect the characters from interpretation by the Unix shell.

Different from Lisp, neither of the above idioms will compile and load the generated C++ code. Instead you have to use the Java compiler to compile and Java to run the compiled

Java sources. First change into the top-level native Java directory native/java and then compile and run the Hello World system like this:

```
% cd native/java/
% javac edu/isi/hello_world/*.java
% java edu.isi.hello_world.HelloWorld
Hello World A
Hello World B
bye
```

It is not necessary to Java-compile STELLA first, since STELLA already ships with a Java compilation of the STELLA system.

4.2 Incrementally Developing STELLA Code

The preferred method of STELLA code development is to use a Lisp-based version of STELLA for all the prototyping and testing, since that allows you to exploit most (or all) of the rapid-prototyping advantages of Lisp. Once a system has reached a certain point of stability, it can be translated into C++ or Java for delivery or to interface it with other C++ or Java code.

In the following, we assume an X/Emacs-based Lisp development environment such as the Allegro CL Emacs interface, where Lisp is run in an Emacs subprocess, and Lisp source can be compiled and evaluated directly from the source buffers. By "Lisp buffer" we mean the listener buffer in which Lisp is actually running, and by "source buffer" we mean a buffer that is used to edit a file that contains STELLA source.

Included in the distribution is the Hello World system comprised of the files

```
sources/systems/hello-world-system.ste
sources/hello-world/file-a.ste
sources/hello-world/file-b.ste
```

To get started, simply add your code to either file-a.ste or file-b.ste, since all the necessary definitions and directories for these files are already set up properly. See section ??? on how to setup your own system.

Make sure the Hello World system is loaded into Lisp by doing the following:

```
(make-system "hello-world" :common-lisp)
```

This will make sure that the system definition is loaded and the necessary module definition is evaluated.

Now suppose you add the following function to file-a.ste:

There are various options for translating and evaluating this definition. For example, you can simply remake the complete system similar to what you would do for a C++ or Java program:

```
(make-system "hello-world" :common-lisp)
```

This will retranslate the modified files, recompile them and reload them into your Lisp image.

Instead of retranslating and recompiling everything, you can incrementally evaluate the definition of factorial from your Emacs-to-Lisp interface. Simply put your cursor somewhere inside the definition in the source buffer and evaluate it by typing M-C-x. This translates the STELLA code into Lisp and compiles (or evaluates) the resulting Lisp code. Now you can actually try it out in the Lisp buffer, for example:

```
STELLA(4): (factorial 6) 720
```

Finally, instead of evaluating the definition in the source buffer, you can also enter it directly at the Lisp prompt with the same effect.

The way this works is that the Lisp symbol stella::defun is actually bound to a Lisp macro that calls all the necessary translation machinery to convert the STELLA defun into Lisp code. Look at the file sources/stella/cl-lib/stella-to-cl.ste for the complete set of such macros. This might be a bit confusing, since there are now three different bindings (or meanings) of defun:

- 1. The STELLA operator defun used to define STELLA functions.
- 2. The Lisp macro stella::defun that resides in the STELLA Lisp package and is only available for convenience in Lisp versions of STELLA.
- 3. The Lisp macro CL:defun which is the standard Common Lisp macro used to define Lisp functions.

We'll try to explicitly qualify which meaning is used wherever there might be some doubt which one is meant. In general, every unqualified symbol mentioned below is either part of the STELLA language or resides in the STELLA Lisp package.

Since a newly-written STELLA function might have errors, it is prudent to first only translate it without actually executing the result of the translation. In the source buffer you can do that by macro-expanding the defun. For example, if you use the Allegro CL interface you would position the cursor on the opening parenthesis of the defun and then type M-M. Any errors discovered by the STELLA translator are reported in the Lisp buffer window. The expansion will be a CL:progn that contains the translated definition as the first element plus various startup-time (initialization) code following it.

In the Lisp buffer you can achieve a similar effect with the lptrans macro. For example, executing

in the Lisp buffer first Lisp-translates the definition, and then prints the translation. To see the C++ translation you can use cpptrans, calling jptrans will generate the Java translation.

You can also use lptrans/cpptrans/jptrans to translate code fragments that are not top-level definitions such as defun and its friends. For example:

```
STELLA(8): (lptrans
```

```
(foreach element in (list 1 2 3)
                do (print element EOL)))
(CL:LET* ((ELEMENT NULL)
          (ITER-003
           (%THE-CONS-LIST (LIST (WRAP-INTEGER 1) (WRAP-INTEGER 2)
                                  (WRAP-INTEGER 3)))))
  (CL:LOOP WHILE (CL:NOT (CL:EQ ITER-003 NIL)) DO
           (CL:PROGN (SETQ ELEMENT (%%VALUE ITER-003))
                     (SETQ ITER-003 (%%REST ITER-003)))
           (%%PRINT-STREAM (%NATIVE-STREAM STANDARD-OUTPUT)
                           ELEMENT EOL)))
()
STELLA(9): (cpptrans
            (foreach element in (list 1 2 3)
                do (print element EOL)))
{ Object* element = NULL;
  Cons* iter004 = list(3, wrapInteger(1), wrapInteger(2),
                          wrapInteger(3))-> theConsList;
 while (!(iter004 == NIL)) {
    element = iter004->value;
    iter004 = iter004->rest;
    cout << element << endl;</pre>
  }
}
:VOID
STELLA(10): (jptrans
             (foreach element in (list 1 2 3)
                 do (print element EOL)))
{ Stella_Object element = null;
  Cons iter005 = Stella.list
                  (Stella_Object.cons
                    (IntegerWrapper.wrapInteger(1),
                     Stella_Object.cons
                      (IntegerWrapper.wrapInteger(2),
                       Stella_Object.cons
                         (IntegerWrapper.wrapInteger(3),
                         Stella.NIL)))).theConsList;
  while (!(iter005 == Stella.NIL)) {
      element = iter005.value;
      iter005 = iter005.rest;
    java.lang.System.out.println(element);
  }
```

```
}
:VOID
```

The use of lptrans is really necessary here, since there is no Lisp macro foreach that knows how to translate STELLA foreach loops (those Lisp macros only exist for top-level definition commands such as defun). In order to translate such code fragments without error messages, they need to be self-contained, i.e., all referenced variables have to be either bound by a surrounding let, or they must be globally defined variables. Otherwise, the STELLA translator will generate various "undefined variable" error messages.

You can use the STELLA Lisp macro eval (i.e., stella::eval not CL:eval) to actually execute such a code fragment. For example:

This translates the loop and executes the result, which prints the wrapped numbers (hence, the |L| prefix) to standard output. The () at the end is the resulting Lisp value returned by the loop (in Lisp everything returns a value, even though for STELLA foreach is a statement, not an expression).

Make it a habit to wrap eval around any STELLA code you incrementally evaluate in the Lips buffer. This makes sure that all the arguments to a function, etc., are translated into the appropriate STELLA objects. For example, evaluating

```
(eval (list :a :b :c))
```

in the Lisp buffer generates a STELLA list that points to the STELLA keywords :a, :b and :c. If you don't use eval, for example,

```
(list :a :b :c)
```

a STELLA list containing the Lisp keywords ':a', ':b' and ':c' will be created. Lisp keywords are a completely different data structure than STELLA keywords, and any STELLA code expecting a STELLA keyword but finding a Lisp keyword will break, since Lisp keywords are not a legal STELLA data structure. Unfortunately, such cases can be very confusing, since Lisp and STELLA keywords look/print exactly alike.

eval is also necessary to access STELLA symbols and surrogates in the Lisp buffer. For example, to access a STELLA symbol, you can use quote (again, this is the STELLA quote not CL:quote):

```
(eval (quote foo))
```

This returns the STELLA symbol foo. We explicitly used quote here, since code typed at the Lisp prompt is first passed through the Lisp reader before the STELLA translator sees it, and the default Lisp reader interprets the 'character differently than the STELLA reader. Within a STELLA file you can use the syntax 'foo, since it will be read directly by the STELLA reader that knows how to interpret it correctly.

lptrans, cpptrans and jptrans are evaluable STELLA commands that can also be evaluated by the C++ and Java version of STELLA. For example, to generate a Java trans-

lation of a little STELLA code fragment you could run the stella script in the STELLA directory like this (the output below has been additionally indented by hand for clarity):

```
% ./stella -e '(jptrans
                 (foreach element in (list 1 2 3)\
                    do (print element EOL)))'
Running C++ version of STELLA...
Welcome to STELLA 3.4.0
{ Stella_Object element = null;
  Cons iter001 = Stella.list
                  (Stella_Object.cons
                    (IntegerWrapper.wrapInteger(1),
                     Stella_Object.cons
                      (IntegerWrapper.wrapInteger(2),
                       Stella_Object.cons
                        (IntegerWrapper.wrapInteger(3),
                         Stella.NIL)))).theConsList;
 while (!(iter001 == Stella.NIL)) {
    {
      element = iter001.value;
      iter001 = iter001.rest;
    }
    java.lang.System.out.println(element);
}
```

4.3 Performance Hints

Here are a few things to watch out for once you get serious about the performance of your translated STELLA programs:

Safety checks: The STELLA variable *safety* controls whether certain safety code is added to your translated STELLA program. For Lisp translations it also controls whether cast's will be translated into run-time type checks or not. There is no run-time type checking performed in C++. In Java native casts will always perform runtime type tests. The default *safety* level is 3 which enables the translation of all safety clauses with level 3 or lower. A safety level of 1 or lower disables the generation of calls to the cast function in Lisp. cast performs run-time type checks which are somewhat expensive. However, you should not disable run-time type checking in Lisp until you have fully debugged your program. Once you are confident that your program works correctly, you can set *safety* to 0 before you translate it. That way you will avoid the generation and execution of any safety code at all. All of the core STELLA system was translated with *safety* set to 1.

Quoted cons trees: Access to quoted constants that are not symbols is somewhat slow, since it currently uses hashing to find them in a table. Hence, access to quoted constants such as (quote (foo bar fum)) should be avoided in inner loops. Access to quoted symbols such as (quote foo) is fast and does not cause any performance problems. The use of quote for constant cons trees is rare in STELLA (and somewhat deprecated), which is the reason

why this mechanism is not all that well supported. Future versions of STELLA might re-implement the handling of constants and alleviate this performance problem.

Equality tests: The standard equality test in STELLA is eq1?, which the translator will translate into the most efficient equality test for the particular types of operands (eq1? is somewhat similar to the Lisp function CL:eq1 with the exception of comparing strings). If the translator can determine that at least one of the operands is a subtype of STANDARD-OBJECT, it will translate the test into a fast pointer comparison with the Lisp function CL:eq or the C++/Java == operator. However, if both operands are of type OBJECT, they might be wrapped literals such as wrapped integers or strings. In that case the equality test translates into a call to the function eq1? which in turn uses method calls to handle comparison of different types of wrapped literals (two wrapped literals are equal if their wrapped content is equal). This is of course a lot less efficient than a simple pointer comparison. It also means that if you can restrict the type of a variable that will be tested with eq1? to STANDARD-OBJECT, you probably should do so for performance reasons.

Type tests: Run-time type tests as used implicitly within a typecase or explicitly with functions such as cons? have to use a call to the method primary-type. Hence, in performance-critical portions of your code you should try to keep the number of such tests as small as possible.

Wrapping and unwrapping literals: The STELLA translator automatically wraps (or objectifies) literals such as numbers or strings when they are stored in a variable or slot of type OBJECT. Similarly, it unwraps wrapped literals automatically to operate on the literal directly. This is very convenient, since it relieves the programmer from having to perform these conversions by hand and makes the code less cluttered. For example, consider the following code fragment:

Notice how the string literal "foo" is first wrapped so it can be inserted into the CONS list 1 and then automatically unwrapped in the call to concatenate. While this is very convenient, it does cause a certain overhead that should be avoided in performance critical loops, etc. In such situations, it often helps to use auxiliary variables of the appropriate literal type to avoid unnecessary wrap/unwrap operations.

Lisp-style property lists: Lisp programs often use property lists for fast retrieval of information that is linked to symbols. To support the easy translation of existing Lisp programs that use this paradigm into STELLA, a similar mechanism implemented by the functions symbol-value, symbol-plist, and symbol-property is available that preserves the performance benefits of this storage scheme (see the file sources/stella/symbols.ste).

However, property lists do not fit the object-oriented programming paradigm supported by STELLA, and, hence, are frowned upon.

Compiler optimization: The optimization settings used with the native Lisp or C++ compiler can greatly influence performance results. In particular, using high optimization settings with the Lisp compiler can greatly improve slot access time on STELLA objects.

4.3.1 Lisp Performance Hints

The standard Lisp implementation for STELLA objects are CLOS objects, since CLOS provides the most natural Lisp implementation for the STELLA object system. However, there is a price to pay, since in Lisp slot access on CLOS objects is a lot slower than slot access on structs. For example, in Allegro CL 4.3, the access to the value slot of a STELLA CONS cell takes about 4 times longer on a CLOS object implementation of CONS than on a struct implementation. Unfortunately, the struct implementation itself takes about 3 times longer than calling CL:car on a Lisp cons, which is why we are actually using Lisp conses as the Lisp implementation for STELLA CONSes. Note, that in the C++ and Java translation these slot-access performance problems are nonexistent.

In order to get the maximum performance out of the Lisp version of STELLA, you can tell the translator to use structs as the implementation for STELLA objects. It does so by using CL:defstruct instead of CL:defclass and dispatches methods directly on the structure object.

To use the struct translation scheme evaluate

```
(set-stella-feature :use-common-lisp-structs)
```

before you translate a STELLA system. This will generate translated files with a .slisp extension. Make sure that after you translated all the files you are interested in, you disable the above feature with

```
(unset-stella-feature :use-common-lisp-structs)
```

Otherwise, subsequent incremental translations in that Lisp image might fail, since different translation schemes cannot be mixed. If you already are using the struct version of STELLA, all systems will be translated in struct mode by default.

To use the struct translation of your system you have to use the struct version of STELLA. To do so do the following:

```
(CL:setq cl-user::*load-cl-struct-stella?* CL:t)
(CL:load "load-stella.lisp")
```

Alternatively, you can edit the initial value of the variable *load-cl-struct-stella?* in the file load-stella.lisp (see also Section 2.3 [Lisp Installation], page 4).

The reasons why the struct translation scheme is not enabled by default are the following:

• Incremental redefinition of STELLA classes does not redefine any objects created with the old definition, and, hence, slot accessors might simply break or retrieve the value of a different slot when applied to such an old object. The programmer therefore has to be very careful when redefining a STELLA class while in struct mode. This means, that you should view the usage of the struct-translation scheme for Lisp as a kind of delivery option, similar to translating into C++. Part of the reason why slot access on CLOS object is expensive is the indirection machinery that allows redefinition of classes and their associated instances. This is great for code development, but the flexibility and expense is usually not needed or warranted for delivered code.

• The performance trade-offs between CLOS and struct versions might be different in different versions of Lisp. For example, in older version of Allegro CL slot access on structs was fast, but method dispatch was significantly slower than for CLOS objects which eliminated some/all of the performance gains.

5 Library Classes (tbw)

To be written.

6 Library Functions

6.1 Basic Constants and Predicates

null? (x): BOOLEAN [Method on OBJECT] Return true if x is undefined (handled specially by all translators).

null? (x): BOOLEAN [Method on SECOND-CLASS-OBJECT] Return true if x is undefined (handled specially by all translators).

null? (x): BOOLEAN [Method on NATIVE-VECTOR] Return true if x is undefined (handled specially by all translators).

null? (x): BOOLEAN [Method on STRING] Return true if x is undefined (handled specially by all translators).

null? (x): BOOLEAN [Method on MUTABLE-STRING] Return true if x is undefined (handled specially by all translators).

 $\begin{array}{ll} \textbf{null? (x): BOOLEAN} & [\text{Method on CHARACTER}] \\ \text{Return true if x is undefined (handled specially by all translators).} \end{array}$

null? (x): BOOLEAN [Method on CODE] Return true if x is undefined (handled specially by all translators).

null? (x): BOOLEAN [Method on INTEGER] Return true if x is undefined (handled specially by all translators).

null? (x): BOOLEAN [Method on FLOAT] Return true if x is undefined (handled specially by all translators).

defined? (x): BOOLEAN [Method on OBJECT] Return true if x is defined (handled specially by all translators).

defined? (x): BOOLEAN [Method on SECOND-CLASS-OBJECT] Return true if x is defined (handled specially by all translators).

defined? (x): BOOLEAN [Method on NATIVE-VECTOR] Return true if x is defined (handled specially by all translators).

 $\begin{array}{ll} \textbf{defined? (x): BOOLEAN} & [Method \ on \ STRING] \\ & \text{Return true if } x \ \text{is defined (handled specially by all translators).} \end{array}$

defined? (x): BOOLEAN [Method on MUTABLE-STRING] Return true if x is defined (handled specially by all translators).

defined? (x): BOOLEAN [Method on CHARACTER]
Return true if x is defined (handled specially by all translators).

defined? (x): BOOLEAN

[Method on INTEGER]

Return true if x is defined (handled specially by all translators).

defined? (x): BOOLEAN

[Method on FLOAT]

Return true if x is defined (handled specially by all translators).

eq? ((x UNKNOWN) (y UNKNOWN)): BOOLEAN

[Function]

Return true if x and y are literally the same object (or simple number). Analogue to the Common Lisp EQL and C++ and Java's ==-.

eql? ((x OBJECT) (y OBJECT)): BOOLEAN

[Function]

Return true if x and y are eq? or equivalent literals such as strings that also might be wrapped in non-identical wrappers. For the case where x or y are plain literals such as strings or integers, the STELLA translator substitutes the equality test appropriate for the particular target language and does not actually call this function. For cases where x or y are known to be of type STANDARD-OBJECT, the STELLA translator substitutes the faster eq? test inline.

equal? $((x ext{ OBJECT}) (y ext{ OBJECT}))$: BOOLEAN

[Function]

Return true if x and y are eq1? or considered equal by a user-defined object-equal? method. This implements a fully extensible equality test similar to Java's equals method. Note that writers of custom object-equal? methods must also implement a corresponding equal-hash-code method.

object-equal? (x (y OBJECT)) : BOOLEAN

[Method on OBJECT]

Return true if x and y are eq?.

object-equal? (x (y OBJECT)) : BOOLEAN

[Method on WRAPPER]

Return true if x and y are literal wrappers whose literals are considered eq1?.

6.2 Numbers

pi : FLOAT

[Constant]

A float approximation of the mathematical constant pi.

+ (&rest (arguments Number)): Number

[Function]

Return the sum of all arguments.

- ((x number) & rest (arguments number)): number

[Function]

If only x was supplied return the result of 0 - x. Otherwise, return the result of (...((x - arg1) - arg2) - ... - argN).

* (&rest (arguments number)): number

[Function]

Return the product of all arguments.

/ ((x NUMBER) & rest (arguments NUMBER)) : NUMBER

[Function]

If only x was supplied return the result of 1 / x. Otherwise, return the result of (...((x / arg1) / arg2) / ... / argN).

1+ ((expression object)): object

[Macro]

Add 1 to expression and return the result.

1- ((expression object)): object Subtract 1 from expression and return the result.	[Macro]
++ ((place object) &body (increment cons)): object Increment the value of place and return the result. place can be either name or a slot reference. Increment by the optional increment (which can or 1 otherwise.	
((place object) &body (decrement cons)): object Decrement the value of place and return the result. place can be either name or a slot reference. Decrement by the optional decrement (which can or 1 otherwise.	
= $((x \text{ NUMBER}) (y \text{ NUMBER}))$: BOOLEAN Return true if x and y are numbers of exactly the same magnitude.	[Function]
< ((x NUMBER) (y NUMBER)) : BOOLEAN Return true if x is less than y .	[Function]
<= $((x \text{ NUMBER}) (y \text{ NUMBER}))$: BOOLEAN Return true if x is less than or equal to y.	[Function]
>= $((x \text{ NUMBER}) (y \text{ NUMBER}))$: BOOLEAN Return true if x is greater than or equal to y.	[Function]
> ((x number) (y number)) : BOOLEAN Return true if x is greater than y.	[Function]
zero? Not yet implemented.	[???]
plus? Not yet implemented.	[???]
even? Not yet implemented.	[???]
odd? Not yet implemented.	[???]
div Not yet implemented.	[???]
rem Not yet implemented.	[???]
mod Not yet implemented.	[???]
gcd ((x LONG-INTEGER) (y LONG-INTEGER)): LONG-INTEGER Return the greatest common divisor of x and y .	[Function]

ceiling ((n NUMBER)): INTEGER Return the smallest integer >= n .	[Function]
floor ($(n \text{ NUMBER})$): INTEGER Return the biggest integer $\leq n$.	[Function]
round ((n NUMBER)): INTEGER Round n to the closest integer and return the result.	[Function]
abs (x) : INTEGER Return the absolute value of x .	[Method on INTEGER]
abs (x) : FLOAT Return the absolute value of x .	[Method on FLOAT]
min Not yet implemented.	[???]
max Not yet implemented.	[???]
$\operatorname{sqrt}((n \operatorname{FLOAT})) : \operatorname{FLOAT}$ Return the square root of n .	[Function]
exp $((n \text{ FLOAT}))$: FLOAT Return the e to the power n .	[Function]
expt ((x float) (y float)) : float Return $x \hat{y}$.	[Function]
$\log ((n \text{ FLOAT}))$: FLOAT Return the natural logarithm (base e) of n .	[Function]
log10 ((n FLOAT)) : FLOAT Return the logarithm (base 10) of n .	[Function]
sin ((n FLOAT)) : FLOAT Return the sine of n radians.	[Function]
cos $((n \text{ FLOAT}))$: FLOAT Return the cosine of n radians.	[Function]
tan $((n \text{ FLOAT}))$: FLOAT Return the tangent of n radians.	[Function]
asin $((n \text{ FLOAT}))$: FLOAT Return the arcsine of n in radians.	[Function]
acos $((n \text{ FLOAT}))$: FLOAT Return the arccosine of n in radians.	[Function]
atan $((n \text{ FLOAT}))$: FLOAT Return the arc tangent of n in radians.	[Function]

atan2 ((x FLOAT) (y FLOAT)): FLOAT Return the arc tangent of x / y in radians. [Function]

random ((n integer)) : integer

[Function]

Generate a random integer in the interval [0..n-1]. The random number generator is seeded based on the current time every time STELLA starts up; however, your mileage may vary depending on the native language implementation.

integer-to-string ((i LONG-INTEGER)) : STRING

[Function]

Convert i to its string representation and return the result. This is more efficient than using a string stream.

string-to-integer ((string STRING)) : LONG-INTEGER

[Function]

Convert a *string* representation of an integer into an integer. Use parse-long-integer if the syntax of *string* needs to be checked for errors.

float-to-string ((f FLOAT)): STRING

[Function]

Convert f to its string representation and return the result. This is more efficient than using a string stream.

string-to-float ((string STRING)) : FLOAT

[Function]

Convert a *string* representation of a float into a float. Use parse-float if the syntax of *string* needs to be checked for errors.

format-float ((f FLOAT) (nDecimals INTEGER)) : STRING

[Function]

Print f in fixed-point format with nDecimals behind the decimal point and return the result as a string.

wrap-integer ((value INTEGER)) : INTEGER-WRAPPER

[Function]

Return a literal object whose value is the INTEGER value.

unwrap-integer ((wrapper INTEGER-WRAPPER)) : INTEGER

[Function]

Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

wrap-float ((value FLOAT)) : FLOAT-WRAPPER

[Function]

Return a literal object whose value is the FLOAT value.

unwrap-float ((wrapper FLOAT-WRAPPER)) : FLOAT

[Function]

Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

6.3 Characters

character-code ((ch CHARACTER)): INTEGER

[Function]

Return the 8-bit ASCII code of *ch* as an integer.

code-character ((code integer)) : CHARACTER

[Function]

Return the character encoded by code (0 \leq code \leq 255).

digit-character? ((ch CHARACTER)) : BOOLEAN

[Function]

Return TRUE if *ch* represents a digit.

letter-character? ((ch Character)) : BOOLEAN Return TRUE if *ch* represents a letter.

[Function]

upper-case-character? ((ch CHARACTER)) : BOOLEAN Return TRUE if *ch* represents an upper-case character. [Function]

lower-case-character? ((ch CHARACTER)) : BOOLEAN Return TRUE if *ch* represents a lower-case character.

[Function]

white-space-character? ((ch CHARACTER)) : BOOLEAN Return TRUE if ch is a white space character.

[Function]

[Function]

character-downcase ((ch CHARACTER)) : CHARACTER If ch is lowercase, return its uppercase version, otherwise, return ch unmodified.

character-upcase ((ch CHARACTER)) : CHARACTER

[Function]

If ch is uppercase, return its lowercase version, otherwise, return ch unmodified. If only the first character of a sequence of characters is to be capitalized, character-capitalize should be used instead.

character-capitalize ((ch Character)) : Character Return the capitalized character for ch. This is generally the same as the uppercase

character, except for obscure non-English characters in Java. It should be used if only the first character of a sequence of characters is to be capitalized.

character-to-string ((c CHARACTER)) : STRING

[Function]

[Function]

Convert c into a one-element string and return the result.

wrap-character ((value CHARACTER)) : CHARACTER-WRAPPER Return a literal object whose value is the CHARACTER value. [Function]

unwrap-character ((wrapper CHARACTER-WRAPPER)) : CHARACTER [Function] Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

6.4 Strings

string-eql? ((x STRING) (y STRING)) : BOOLEAN

[Function]

Return true if x and y are equal strings or are both undefined. This test is substituted automatically by the STELLA translator if eq1? is applied to strings.

string-equal? ((x STRING) (y STRING)) : BOOLEAN

[Function]

Return true if x and y are equal strings ignoring character case or are both undefined.

empty? (x): BOOLEAN

[Method on STRING]

Return true if x is the empty string ""

non-empty? (x): BOOLEAN

[Method on STRING]

Return true if x is not the empty string ""

first (self): CHARACTER

Return the first character of self (settable via setf).

[Method on MUTABLE-STRING]

string-compare ((x STRING) (y STRING) (case-sensitive? BOOLEAN)): [Function] INTEGER Compare x and y lexicographically, and return -1, 0, or 1, depending on whether x is less than, equal, or greater than y. If case-sensitive? is true, then case does matter for the comparison string < ((x STRING) (y STRING)) : BOOLEAN [Function] Return true if x is lexicographically $\langle y \rangle$, considering case. string<= ((x STRING) (y STRING)) : BOOLEAN</pre> [Function] Return true if x is lexicographically $\leq y$, considering case. string>= ((x STRING) (y STRING)) : BOOLEAN [Function] Return true if x is lexicographically $\geq y$, considering case. string> ((x STRING) (y STRING)) : BOOLEAN [Function] Return true if x is lexicographically > y, considering case. string-less? ((x STRING) (y STRING)) : BOOLEAN [Function] Return true if x is lexicographically $\langle y$, ignoring case. string-less-equal? ((x STRING) (y STRING)) : BOOLEAN [Function] Return true if x is lexicographically $\leq y$, ignoring case. string-greater-equal? ((x STRING) (y STRING)) : BOOLEAN [Function] Return true if x is lexicographically $\geq y$, ignoring case. string-greater? ((x STRING) (y STRING)) : BOOLEAN [Function] Return true if x is lexicographically > y, ignoring case. all-upper-case-string? ((s STRING)) : BOOLEAN [Function] Return TRUE if all letters in s are upper case. all-lower-case-string? ((s STRING)) : BOOLEAN [Function] Return TRUE if all letters in s are lower case. make-string ((size integer) (initchar Character)) : STRING [Function] Return a new string filled with size initchars. make-mutable-string ((size INTEGER) (initchar CHARACTER)): [Function] MUTABLE-STRING Return a new mutable string filled with size initchars. make-raw-mutable-string ((size INTEGER)): MUTABLE-STRING [Function] Return a new uninitialized mutable string of size. first (self): CHARACTER [Method on STRING] Return the first character of self.

second (self): CHARACTER

[Method on STRING]

Return the second character of self.

second (self): CHARACTER

[Method on MUTABLE-STRING]

Return the second character of self (settable via setf).

third (self): CHARACTER

[Method on STRING]

Return the third character of self.

third (self): CHARACTER

[Method on MUTABLE-STRING]

Return the third character of self (settable via setf).

fourth (self): CHARACTER

[Method on STRING]

Return the fourth character of self.

fourth (self): CHARACTER

[Method on MUTABLE-STRING]

Return the fourth character of self (settable via setf).

fifth (self): CHARACTER

[Method on STRING]

Return the fifth character of self.

fifth (self): CHARACTER

[Method on MUTABLE-STRING]

Return the fifth character of self (settable via setf).

nth (self (position integer)): Character

[Method on STRING]

Return the character in self at position.

nth (self (position integer)): Character

[Method on MUTABLE-STRING]

Return the character in self at position.

rest (self): STRING

[Method on STRING]

Not documented.

length (self): INTEGER

[Method on STRING]

Return the length of the string self.

length (self): INTEGER

[Method on MUTABLE-STRING]

Return the length of the string self.

member? (self (char Character)): BOOLEAN

[Method on STRING]

Not documented.

INTEGER

position (string (character Character) (start integer)):

[Method on STRING]

Return the position of character within string (counting from zero); or return NULL if character does not occur within string. If start was supplied as non-NULL, only consider the substring starting at start, however, the returned position will always be

relative to the entire string.

last-position (string (character CHARACTER)

[Method on STRING]

(end integer)): integer

Return the last position of *character* within *string* (counting from zero); or return NULL if *character* does not occur within *string*. If *end* was supplied as non-NULL, only consider the substring ending at *end*, however, the returned position will always be relative to the entire string.

string-search ((string STRING) (substring STRING) (start INTEGER)) : [Function]

Return start position of the left-most occurrence of *substring* in *string*, beginning from *start*. Return NULL if it is not a substring. The comparison is exact.

copy (string): STRING

[Method on STRING]

Return a copy of string.

string-upcase ((string STRING)): STRING Return an upper-case copy of string.

[Function]

string-downcase ((string STRING)): STRING

[Function]

Return a lower-case copy of string.

string-capitalize ((string STRING)) : STRING

[Function]

Return a capitalized version of string.

concatenate (string1 (string2 STRING)

[Method on STRING]

&rest (otherStrings string)) : string

Return a new string representing the concatenation of *string1*, *string2*, and *otherStrings*. The two mandatory parameters allow us to optimize the common binary case by not relying on the somewhat less efficient variable arguments mechanism.

subsequence (string (start integer) (end integer)):
STRING

[Method on STRING]

Return a substring of *string* beginning at position *start* and ending up to but not including position *end*, counting from zero. An *end* value of NULL stands for the rest of the string.

remove (string (char CHARACTER)): STRING

[Method on STRING]

Remove all occurences of *char* from *string*.

substitute (self (new-char CHARACTER)

[Method on STRING]

(old-char Character)): String

Substitute all occurences of old-char with new-char in the string self.

substitute (self (new-char CHARACTER)

[Method on MUTABLE-STRING]

(old-char character)): Mutable-String

Substitute all occurrences of old-char with new-char in the string self.

replace-substrings ((string STRING) (new STRING) (old STRING)): [Function]

Replace all occurrences of old in string with new.

instantiate-string-template ((template STRING)

[Function]

&rest (vars&values STRING)) : STRING

For each occurrence of a <var> string from vars&values in template replace it with its corresponding <value> string. Replacement is done in sequence which means (part of) a value might be replaced further with a later <var> and <value>.

insert-string ((source STRING) (start INTEGER) (end INTEGER)

[Function]

(target mutable-string) (target-index integer)

(case-conversion KEYWORD)): INTEGER

Inserts characters from source begining at start and ending at end into target starting at target-index. If end is null, then the entire length of the string is used. The copy of characters is affected by the case-conversion keyword which should be one of :UPCASE :DOWNCASE :CAPITALIZE :PRESERVE.

The final value of target-index is returned.

wrap-string ((value STRING)) : STRING-WRAPPER

[Function]

Return a literal object whose value is the STRING value.

wrap-mutable-string ((value MUTABLE-STRING)):

[Function]

MUTABLE-STRING-WRAPPER

Return a literal object whose value is the MUTABLE-STRING value.

unwrap-string ((wrapper STRING-WRAPPER)) : STRING

[Function]

Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

unwrap-mutable-string ((wrapper MUTABLE-STRING-WRAPPER)): [Function] MUTABLE-STRING

Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

string-to-mutable-string ((s STRING)): MUTABLE-STRING

[Function]

Copy s into a mutable string with the same content. In Lisp and C++ this simply copies s.

mutable-string-to-string ((s MUTABLE-STRING)) : STRING

[Function]

Convert s into a regular string with the same content. In Lisp and C++ this is a no-op.

integer-to-string ((i LONG-INTEGER)) : STRING

[Function

Convert i to its string representation and return the result. This is more efficient than using a string stream.

string-to-integer ((string STRING)) : LONG-INTEGER

[Function]

Convert a *string* representation of an integer into an integer. Use parse-long-integer if the syntax of *string* needs to be checked for errors.

float-to-string ((f FLOAT)): STRING

[Function]

Convert f to its string representation and return the result. This is more efficient than using a string stream.

string-to-float ((string STRING)) : FLOAT

[Function]

Convert a *string* representation of a float into a float. Use parse-float if the syntax of *string* needs to be checked for errors.

format-float ((f FLOAT) (nDecimals INTEGER)): STRING [Function] Print f in fixed-point format with nDecimals behind the decimal point and return the result as a string.

character-to-string ((c CHARACTER)) : STRING

[Function]

Convert c into a one-element string and return the result.

stringify ((expression object)): String

[Function]

Print expression onto a string and return the result. Printing is done with *printReadably?* set to true and with *printPretty?* set to false.

stringify-in-module ((tree OBJECT) (module MODULE)): STRING [Function] Stringify a parse tree relative to module, or *module* if no module is specified.

unstringify ((string STRING)) : OBJECT

[Function]

Read a STELLA expression from *string* and return the result. This is identical to read-s-expression-from-string.

unstringify-in-module ((string STRING) (module MODULE)): [Function]
OBJECT

Unstringify relative to module, or *MODULE* if no module is specified.

6.5 CONS Lists and Trees

 ${
m CONS}$: STANDARD-OBJECT

[Class]

Not documented.

any-value : OBJECT

[Class Parameter of]

Not documented.

value : (LIKE (ANY-VALUE SELF))

[Slot of]

Not documented.

rest : (CONS OF (LIKE (ANY-VALUE SELF)))

[Slot of]

Not documented.

nil : CONS

[Variable]

Not documented.

empty? (self): BOOLEAN

[Method on CONS]

Return true iff self equals nil.

non-empty? (self): BOOLEAN

[Method on CONS]

Return true iff self is not equal to nil.

nil? ((x OBJECT)) : BOOLEAN

[Function]

Return true iff x equals nil.

equal-cons-trees? ((tree1 object) (tree2 object)): Boolean [Function] Return true iff the cons trees tree1 and tree2 are structurally equivalent. Uses an eq1? test.

object-equal? (tree1 (tree2 OBJECT)): BOOLEAN [Method on CONS] Return true iff the cons trees tree1 and tree2 are structurally equivalent. Uses equal? to test equality of subtrees.

equal-hash-code (self): INTEGER [Method on CONS] Return an equal? hash code for self. Note that this is O(N) in the number of elements of self.

cons ((value object) (rest cons)) : cons
Return a cons record that points to value and rest.

[Function]

first (self): (LIKE (ANY-VALUE SELF)) [Method on CONS]
Return the first element of self. The first element of self can be set with setf. Note that (first NIL) = null.

third (self): (LIKE (ANY-VALUE SELF)) [Method on CONS] Return the third element of self. The third element of self can be set with setf. Note that (third NIL) = null.

fourth (self): (LIKE (ANY-VALUE SELF)) [Method on CONS]
Return the fourth element of self. The fourth element of self can be set with setf.
Note that (fourth NIL) = null.

fifth (self): (LIKE (ANY-VALUE SELF)) [Method on CONS]
Return the fifth element of self. The fifth element of self can be set with setf. Note, that (fifth NIL) = null.

nth (self (position integer)): (LIKE (ANY-VALUE SELF)) [Method on CONS] Return the element of self at position. The nth element of self can be set with setf. Note, that (nth NIL <pos>) = null.

nth-rest (self (position integer)): (LIKE SELF) [Method on CONS] Apply rest position times to self.

last (self): (LIKE (ANY-VALUE SELF)) [Method on CONS] Return the last element of self.

but-last (self): (ITERATOR OF (LIKE (ANY-VALUE SELF))) [Method on CONS] Generate all but the last element of the cons list self.

last-cons ((self cons)): (CONS OF (LIKE (ANY-VALUE SELF))) [Function] Return the last cons of self.

length (self): INTEGER [Method on CONS]
Return the length of the CONS list self.

member? (self (object OBJECT)): BOOLEAN [Method on CONS] Return true iff object is a member of the cons list self (uses an eql? test).

memb? (self (object OBJECT)): BOOLEAN [Method on CONS]
Return true iff object is a member of the cons list self (uses an eq? test).

position (self (object object) (start integer)): integer [Method on cons] Return the position of object within the cons-list self (counting from zero); or return null if object does not occur within self (uses an eq1? test). If start was supplied as non-'null', only consider the sublist starting at start, however, the returned position will always be relative to the entire list.

last-position (self (object OBJECT) (end INTEGER)): [Method on CONS] INTEGER

Return the position of *object* within the cons-list *self* (counting from zero); or return null if *object* does not occur within *self* (uses an eql? test). If start was supplied as non-'null', only consider the sublist ending at *end*, however, the returned position will always be relative to the entire list.

reverse (self): (LIKE SELF) [Method on CONS]

Destructively reverse the members of the cons list self.

remove (self (value OBJECT)): (LIKE SELF) [Method on CONS]

Destructively remove all entries in the cons list self that match value. Unless the remaining list is nil, insure that the cons that heads the list is unchanged.

remove-duplicates (self): (LIKE SELF) [Method on CONS]

Destructively remove duplicates from self and return the result. Removes all but the first occurrence of items in the list. Preserves the original order of the remaining members. Runs in linear time.

remove-if (self (test? FUNCTION-CODE)): (LIKE SELF) [Method on CONS]

Destructively removes all members of the cons list self for which test? evaluates to true. test takes a single argument of type OBJECT and returns true or false. Returns a cons list. In case the first element is removed, the return result should be assigned to a variable.

substitute (self (inValue object) (outValue object)): cons [Method on cons]

Destructively replace each appearance of outValue by inValue in the cons list self.

concatenate (list1 (list2 cons) &rest (otherLists cons)): [Method on cons]

Return a cons list consisting of the concatenation of *list1*, *list2*, and *otherLists*. The operation is destructive wrt all but the last list argument which is left intact. The two mandatory parameters allow us to optimize the common binary case by not relying on the somewhat less efficient variable arguments mechanism.

append ((consList1 cons) (consList2 cons)): cons

Return a cons list representing the concatenation of consList1 and consList2. The concatenation is NOT destructive.

prepend (self (list1 cons)): cons [Method on cons]

Return a cons list consisting of the concatenation of list1 and self. A copy of list1 is prepended to self. This operation results in structure sharing of self; to avoid this, self should not be pointed to by anything other than the tail of the prepended copy.

pushq ((variable SYMBOL) (value OBJECT)): OBJECT Push value onto the cons list variable. [Macro]

pushq-new ((variable SYMBOL) (value OBJECT)) : OBJECT

[Macro]

Push value onto the cons list variable, unless value is already a member of the list.

popq ((variable symbol)): OBJECT

[Macro]

Pops a value from the cons list variable.

cons-list (&rest (values OBJECT)) : CONS

[Function]

Return a cons list containing values, in order.

list* (&rest (values object)) : cons

[Function]

Return a list of conses that make up the list values, terminated by the last value rather than by nil. Assumes that at least one value is passed in.

copy-cons-list ((self cons)) : (LIKE SELF)

[Function]

Return a copy of the cons list self.

copy-cons-tree ((self object)) : (LIKE SELF)

[Function]

Return a copy of the cons tree self.

substitute-cons-tree ((tree OBJECT) (newValue OBJECT)

[Function]

(oldValue object)): object

Destructively replace each appearance of oldValue by newValue in the cons tree tree. Return the tree. Uses an eql? test.

search-cons-tree? ((tree OBJECT) (value OBJECT)) : BOOLEAN

Function

Return true iff the value value is embedded within the cons tree tree. Uses an eq1? test.

tree-size ((self object)) : INTEGER

[Function]

Not documented.

safe-tree-size ((tree cons)) : INTEGER STRING

[Function]

Not documented.

cons-tree-nth ((tree cons) &rest (index integer)): OBJECT

[Function]

Access an arbitrary element of *tree* identified by a path specified as a list of *index* values. The first *index* specifies the *index*-th element of *tree*, the second *index* the *index*-th subelement of that element, etc. Example:

(cons-tree-nth (quote (a (b (c d e) f) g)) 1 1 2) \Rightarrow e

cons-tree-nth-rest ((tree cons) & rest (index integer)): cons [Function] Access an arbitrary sublist of tree identified by a path specified as a list of index values. The first index specifies the index-th element of tree, the second index the index-th subelement of that element, ..., the last index specifies the nth-rest of the previous element (different from cons-tree-nth). Example:

(cons-tree-nth-rest (quote (a (b (c d e) f) g)) 1 1 1) => (d e)

```
{\tt match-cons-tree} ((tree <code>OBJECT</code>) (pattern <code>OBJECT</code>)
```

[Function]

(bindings key-value-list)): key-value-list

Match pattern against tree and return a list of variable bindings if they match, or NULL otherwise. bindings can be NULL or an initial list of bindings to consider. Pattern variables use KIF syntax, i.e., they need to start with a ? character. A single question mark is interpreted as the anonymous variable. Example:

Variables can't be quoted but quoting can effectively be achieved by inserting to-bequoted variables bound to themselves into *bindings*.

```
cons-tree-match? ((tree OBJECT) (pattern OBJECT)): BOOLEAN [Function]
Predicate version of match-cons-tree (which see).
```

```
consify (self): (CONS OF (LIKE (ANY-VALUE SELF))) [Method on CONS] Return self.
```

```
allocate-iterator (self): (CONS-ITERATOR OF (LIKE [Method on CONS] (ANY-VALUE SELF)))

Not documented.
```

```
next? (self): BOOLEAN
Not documented.
```

[Method on CONS-ITERATOR]

sort (self (predicate function-code)): (cons of (like

```
LIKE [Method on CONS]
```

(ANY-VALUE SELF)))
Perform a stable, destructive sort of self according to predicate, and return the result. If predicate has a < semantics, the result will be in ascending order. It is not guaranteed that self will point to the beginning of the sorted result. If predicate is null, a suitable < predicate is chosen depending on the first element of self, and it is assumed that all elements of self have the same type (supported element types are GENERALIZED-SYMBOL, STRING, INTEGER, and FLOAT).

Just like **sort** but assumes each element of *self* is a tuple (a cons) whose n-th element (0-based) will be used for comparison.

```
map-null-to-nil ((self cons)): (LIKE SELF) [Function]
Return nil iff self is null or self otherwise.
```

```
*printpretty?* : BOOLEAN [Special Variable]

If true conses will be pretty printed.
```

```
*printreadably?* : BOOLEAN [Special Variable]

If true conses will be printed as readable Stella code.
```

printprettycode? : BOOLEAN

[Special Variable]

When true pretty-print Stella and translated code. Since (Lisp) pretty-printing is somewhat slow, turning this off speeds up file translation, but it also makes translated output very unreadable.

6.5.1 CONS Lists as Sets

subset? (self (otherList cons)) : BOOLEAN

[Method on CONS]

Return true if every element of self also occurs in otherList. Uses an eql? test and a simple quadratic-time algorithm. Note that this does not check whether self and otherList actually are sets.

equivalent-sets? (self (otherList cons)) : BOOLEAN

[Method on CONS]

Return true if every element of self occurs in otherList and vice versa. Uses an eq1? test and a simple quadratic-time algorithm. Note that this does not check whether self and otherList actually are sets.

union (self (otherList cons)) : cons

[Method on CONS]

Return the set union of self and otherList. Uses an eq1? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if both self and otherList are sets.

intersection (self (otherList cons)) : cons

[Method on CONS]

Return the set intersection of self and otherList. Uses an eql? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if both self and otherList are sets.

difference (self (otherList cons)) : cons

[Method on CONS]

Return the set difference of *self* and *otherList* (i.e., all elements that are in *self* but not in otherSet). Uses an eq1? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if both *self* and *otherList* are sets.

subtract (self (otherList cons)) : cons

[Method on CONS]

Return the set difference of *self* and *otherList* by destructively removing elements from *self* that also occur in *otherList*. Uses an eq1? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if *self* is a set.

6.6 Lists

LIST : SEQUENCE

[Class]

Not documented.

any-value : OBJECT

[Class Parameter of]

Not documented.

the-cons-list : (CONS OF (LIKE (ANY-VALUE SELF)))

Not documented.

[Slot of]

Not documented

nil-list : LIST

[Variable]

Not documented.

length (self): INTEGER

Not documented.

[Method on LIST]

defined-list? ((self LIST)) : BOOLEAN [Function] Return TRUE unless self is NULL or the NIL-LIST. null-list? ((self LIST)) : BOOLEAN [Function] Return TRUE iff self is NULL or the NIL-LIST. empty? (self): BOOLEAN [Method on LIST] Return TRUE if the list self has no members. non-empty? (self): BOOLEAN [Method on LIST] Return TRUE if the list self has at least one member. object-equal? (x (y OBJECT)) : BOOLEAN[Method on LIST] Return TRUE iff the lists x and y are structurally equivalent. Uses equal? to test equality of elements. equal-hash-code (self): INTEGER [Method on LIST] Return an equal? hash code for self. Note that this is O(N) in the number of elements of self. list (&rest (values object)): List [Function] Return a list containing values, in order. first (self): (LIKE (ANY-VALUE SELF)) [Method on LIST] Return the first item in the list self, or NULL if empty. second (self): (LIKE (ANY-VALUE SELF)) [Method on LIST] Return the second item in the list self, or NULL if empty. third (self): (LIKE (ANY-VALUE SELF)) [Method on LIST] Return the third item in the list self, or NULL if empty. fourth (self): (LIKE (ANY-VALUE SELF)) [Method on LIST] Return the fourth item in the list self, or NULL if empty. fifth (self): (LIKE (ANY-VALUE SELF)) [Method on LIST] Return the fifth item in the list self, or NULL if empty. nth (self (position integer)): (LIKE (ANY-VALUE SELF)) [Method on LIST] Return the nth item in the list self, or NULL if empty. rest (self): (CONS OF (LIKE (ANY-VALUE SELF))) [Method on LIST] Return a cons list of all but the first item in the list self. last (self): (LIKE (ANY-VALUE SELF)) [Method on LIST] Return the last element of self. but-last (self): (ITERATOR OF (LIKE (ANY-VALUE SELF))) [Method on List] Generate all but the last element of the list self.

member? (self (object OBJECT)): BOOLEAN [Method on LIST] Return TRUE iff object is a member of the list self (uses an eql? test).

- memb? (self (object (LIKE (ANY-VALUE SELF)))): BOOLEAN [Method on LIST] Return TRUE iff object is a member of the cons list self (uses an eq? test).
- position (self (object object) (start integer)): integer [Method on List] Return the position of object within the list self (counting from zero); or return NULL if object does not occur within self (uses an eq1? test). If start was supplied as non-NULL, only consider the sublist starting at start, however, the returned position will always be relative to the entire list.
- last-position (self (object OBJECT) (end INTEGER)): INTEGER [Method on LIST] Return the position of object within the list self (counting from zero); or return NULL if object does not occur within self (uses an eq1? test). If end was supplied as non-NULL, only consider the sublist ending at end, however, the returned position will always be relative to the entire list.
- insert (self (value (LIKE (ANY-VALUE SELF)))): [Method on LIST]

 Add value to the front of the list self.
- push (self (value (LIKE (ANY-VALUE SELF)))):

 Add value to the front of the list self.

 [Method on LIST]
- $\begin{array}{ll} \textbf{insert-new} \ (self \ (value \ (\texttt{LIKE} \ (\texttt{ANY-VALUE} \ \texttt{SELF})))): \\ & \textbf{Add} \ value \ to \ the \ front \ of \ the \ list \ self \ unless \ its \ already \ a \ member. \\ \end{array}$
- insert-last (self (value (LIKE (ANY-VALUE SELF)))) : [Method on LIST]
 Insert value as the last entry in the list self.
- reverse (self): (LIKE SELF) [Method on LIST]
 Reverse the members of self (in place).
- remove (self (value (LIKE (ANY-VALUE SELF)))): (LIKE SELF) [Method on LIST]

 Destructively remove all entries in self that match value.
- remove-duplicates (self): (LIKE SELF) [Method on LIST]

 Destructively remove duplicates from self and return the result. Preserves the original order of the remaining members.
- remove-deleted-members (self): (LIKE SELF) [Method on LIST]

 Not documented.
- remove-if (self (test? function-code)): (Like self) [Method on list]

 Destructively remove all members of the list self for which test? evaluates to TRUE.

 test takes a single argument of type OBJECT and returns TRUE or FALSE. Returns self.
- pop (self): (LIKE (ANY-VALUE SELF)) [Method on LIST] Remove and return the first element in the list self. Return NULL if the list is empty.

substitute (self (inValue object) (outValue object)) : (LIKE [Method on LIST] SELF)

Destructively replace each appearance of out Value by in Value in the list self.

concatenate (list1 (list2 LIST) & rest (otherLists LIST)): LIST [Method on LIST] Copy list2 and all otherLists onto the end of list1. The operation is destructive wrt list1, but leaves all other lists intact. The two mandatory parameters allow us to optimize the common binary case by not relying on the somewhat less efficient variable arguments mechanism.

prepend (self (list2 LIST)) : (LIKE SELF)

[Method on List]

Copy list2 onto the front of the list self. The operation is destructive wrt self, but leaves list2 intact.

copy (self): (LIST OF (LIKE (ANY-VALUE SELF))) [Method on LIST] Return a copy of the list self. The conses in the copy are freshly allocated.

clear (self):

[Method on LIST]

Make self an empty list.

consify (self): (CONS OF (LIKE (ANY-VALUE SELF)))
Return a list of elements in self.

[Method on LIST]

allocate-iterator (self): (LIST-ITERATOR OF (LIKE

(ANY-VALUE SELF)))

[Method on LIST]

Not documented.

next? (self): BOOLEAN

[Method on LIST-ITERATOR]

Not documented.

[Method on LIST]

Perform a stable, destructive sort of self according to predicate, and return the result. If predicate has a < semantics, the result will be in ascending order. If predicate is NULL, a suitable < predicate is chosen depending on the first element of self, and it is assumed that all elements of self have the same type (supported element types are GENERALIZED-SYMBOL, STRING, INTEGER, and FLOAT).

```
map-null-to-nil-list ((self LIST)) : LIST
```

[Function]

Return NIL-LIST iff self is NULL or self otherwise.

6.6.1 Lists as Sets

Similar to CONS lists LIST's can also be treated as sets and support the set manipulations below. Note that LIST constructors do not check for proper set-hood and may have surprising results if a list contains duplicate elements.

subset? (self (otherList LIST)) : BOOLEAN

[Method on LIST]

Return true if every element of self also occurs in otherList. Uses an eq1? test and a simple quadratic-time algorithm. Note that this does not check whether self and otherList actually are sets.

equivalent-sets? (self (otherList LIST)) : BOOLEAN

[Method on List]

Return true if every element of *self* occurs in *otherList* and vice versa. Uses an eq1? test and a simple quadratic-time algorithm. Note that this does not check whether *self* and *otherList* actually are sets.

union (self (otherList LIST)) : LIST

[Method on List]

Return the set union of self and otherList. Uses an eq1? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if both self and otherList are sets.

intersection (self (otherList LIST)) : LIST

[Method on List]

Return the set intersection of self and otherList. Uses an eql? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if both self and otherList are sets.

difference (self (otherList LIST)) : LIST

[Method on LIST]

Return the set difference of self and otherList (i.e., all elements that are in self but not in otherSet). Uses an eql? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if both self and otherList are sets.

subtract (self (otherList LIST)) : LIST

[Method on LIST]

Return the set difference of *self* and *otherList* by destructively removing elements from *self* that also occur in *otherList*. Uses an eq1? test and a simple quadratic-time algorithm. Note that the result is only guaranteed to be a set if *self* is a set.

SET is a subclass of LIST that overrides certain LIST operations to prevent duplicate elements. The following additional or modified operations are supported:

SET : LIST, SET-MIXIN

[Class]

Not documented.

any-value : OBJECT

[Class Parameter of]

Not documented.

insert (self (value (LIKE (ANY-VALUE SELF)))) :

[Method on Set]

Add value to the set self unless it is already a member.

push (self (value (LIKE (ANY-VALUE SELF)))):

[Method on SET]

Add value to the front of set self unless it is already a member.

insert-last (self (value (LIKE (ANY-VALUE SELF)))) :

[Method on SET]

Add value to the end of set self unless it is already a member.

substitute (self (new object) (old object)) : (LIKE SELF)

[Method on Set]

Destructively replace old with new in the set self unless new is already a member.

Concatenate (set1 (set2 LIST) &rest (otherSets LIST)): SET [Method on SET] Union set2 and all otherSets onto the end of set1. The operation is destructive wrt set1, but leaves all other sets intact. The two mandatory parameters allow us to optimize the common binary case by not relying on the somewhat less efficient variable arguments mechanism.

object-equal? (x (y OBJECT)) : BOOLEAN

[Method on Set]

Return TRUE iff x and y are SET's with equivalent members. Uses equal? to test equality of elements. This is more general than equivalent-sets?, since that only uses an eql? test.

equal-hash-code (self): INTEGER

[Method on Set]

Return an equal? hash code for self. Note that this is O(N) in the number of elements of self.

set (&rest (values object)) : set

[Function]

Return a set containing values, in order.

6.7 Property and Key-Value Lists

PROPERTY-LIST: DICTIONARY

[Class]

Not documented.

any-key : OBJECT

[Class Parameter of]

Not documented.

any-value : OBJECT

[Class Parameter of]

Not documented.

the-plist : CONS

[Slot of]

Not documented.

empty? (self): BOOLEAN

[Method on PROPERTY-LIST]

Not documented.

non-empty? (self): BOOLEAN

Not documented.

[Method on Property-List]

object-equal? (x (y OBJECT)) : BOOLEAN

[Method on PROPERTY-LIST]

Return TRUE if x and y represent the same set of key/value pairs..

equal-hash-code (self): INTEGER

[Method on Property-List]

Return an equal? hash code for self. Note that this is O(N) in the number of entries of self.

length (self): INTEGER

[Method on Property-List]

Not documented.

lookup (self (key (Like (any-key self)))) : (Like

[Method on PROPERTY-LIST]

(ANY-VALUE SELF))

Not documented.

insert-at (self (key (LIKE (ANY-KEY SELF)))

[Method on PROPERTY-LIST]

(value (LIKE (ANY-VALUE SELF)))):

Insert the entry <'key', value> into the property list self. If a previous entry existed with key key, that entry is replaced.

remove-at (self (key (LIKE (ANY-KEY SELF)))): [Method on Property-List] OBJECT Remove the entry that matches the key key. Return the value of the matching entry, or NULL if there is no matching entry. Assumes that at most one entry matches key. copy (self): (LIKE SELF) [Method on Property-List] Return a copy of the list self. The conses in the copy are freshly allocated. clear (self): [Method on Property-List] Make self an empty property list. allocate-iterator (self): [Method on Property-List] (PROPERTY-LIST-ITERATOR OF (LIKE (ANY-KEY SELF)) (LIKE (ANY-VALUE Not documented. next? (self): BOOLEAN [Method on Property-List-Iterator] Not documented. [Class] KV-CONS: STANDARD-OBJECT Not documented. any-key : OBJECT [Class Parameter of] Not documented. any-value : OBJECT [Class Parameter of] Not documented. key : OBJECT [Slot of] Not documented. [Slot of] value : OBJECT Not documented. rest : KV-CONS [Slot of] Not documented. kv-cons ((key object) (value object) (rest kv-cons)): kv-cons [Function] Create, fill-in, and return a new KV-CONS. copy-kv-cons-list ((kvconslist kv-cons)) : kv-cons [Function] Return a copy of the cons list consList. KEY-VALUE-LIST : DICTIONARY [Class] Not documented. any-key : OBJECT [Class Parameter of] Not documented. any-value : OBJECT [Class Parameter of] Not documented.

new entry.

the-kv-list : KV-CONS [Slot of] Not documented. empty? (self): BOOLEAN [Method on KEY-VALUE-LIST] Not documented. non-empty? (self): BOOLEAN [Method on KEY-VALUE-LIST] Not documented. object-equal? (x (y OBJECT)) : BOOLEAN[Method on KEY-VALUE-LIST] Return TRUE if x and y represent the same set of key/value pairs. equal-hash-code (self): INTEGER [Method on Key-value-list] Return an equal? hash code for self. Note that this is O(N) in the number of entries of self. length (self): INTEGER [Method on KEY-VALUE-LIST] Not documented. lookup (self (key (like (any-key self)))) : (like [Method on KEY-VALUE-LIST] (ANY-VALUE SELF)) Not documented. reverse (self): (LIKE SELF) [Method on KEY-VALUE-LIST] Destructively reverse the members of the list self. insert-at (self (key (LIKE (ANY-KEY SELF))) [Method on KEY-VALUE-LIST] (value (LIKE (ANY-VALUE SELF)))): Insert the entry <'key', value> into the association self. If a previous entry existed with key key, that entry is replaced. remove-at (self (key (LIKE (ANY-KEY SELF)))): [Method on KEY-VALUE-LIST] OBJECT Remove the entry that matches the key key. Return the value of the matching entry, or NULL if there is no matching entry. Assumes that at most one entry matches key. insert-entry (self (key (LIKE (ANY-KEY SELF))) [Method on KEY-VALUE-LIST] (value (LIKE (ANY-VALUE SELF)))): Insert an entry <'key', value > to self unless an identical entry already exists. This can generate duplicate entries for key. remove-entry (self (key (LIKE (ANY-KEY SELF))) [Method on KEY-VALUE-LIST] (value (LIKE (ANY-VALUE SELF)))): Remove the entry that matches <'key', value>. Assumes that more than one entry can match key. push (self (value KV-CONS)) : [Method on KEY-VALUE-LIST] Make value be the new first element of self. Note that the rest slot of value should be

null, since it will be overwritten. This might duplicate an existing entry. If a previous entry existed with the same key as value, that entry is retained, but shadowed by this

equality of elements.

kv-push (self (key (LIKE (ANY-KEY SELF))) [Method on KEY-VALUE-LIST] (value (LIKE (ANY-VALUE SELF)))): Add a new entry <'key', value> to the front of the association self. This might duplicate an existing entry. If a previous entry existed with key key, that entry is retained, but shadowed by this new entry. pop (self): (LIKE (ANY-VALUE SELF)) [Method on KEY-VALUE-LIST] Remove and return the value of the first element of the kv-list self. It does NOT return the KV-CONS object. Return null if the list is empty. copy (self): (LIKE SELF) [Method on KEY-VALUE-LIST] Return a copy of the kv-list self. The kv-conses in the copy are freshly allocated. clear (self): [Method on KEY-VALUE-LIST] Make *self* an empty dictionary. consify (self): (CONS OF (LIKE (ANY-VALUE SELF))) [Method on KEY-VALUE-LIST] Return a list of key-value pairs in self. allocate-iterator (self): (KV-LIST-ITERATOR OF [Method on KEY-VALUE-LIST] (LIKE (ANY-KEY SELF)) (LIKE (ANY-VALUE SELF))) Not documented. next? (self): BOOLEAN [Method on KV-LIST-ITERATOR] Not documented. 6.8 Vectors VECTOR : SEQUENCE [Class] Not documented. any-value : OBJECT [Class Parameter of] Not documented. [Slot of] array-size : INTEGER Not documented. the-array : (NATIVE-VECTOR OF (LIKE (ANY-VALUE SELF))) [Slot of] Not documented. EXTENSIBLE-VECTOR: VECTOR [Class] Not documented. empty? (self): BOOLEAN [Method on VECTOR] Return true if self has length 0. non-empty? (self): BOOLEAN [Method on VECTOR] Return true if self has length > 0. object-equal? (x (y OBJECT)) : BOOLEAN[Method on VECTOR]

Return TRUE iff the vectors x and y are structurally equivalent. Uses equal? to test

Not documented.

equal-hash-code (self): INTEGER [Method on VECTOR] Return an equal? hash code for self. vector (&rest (values object)): Vector [Function] Return a vector containing values, in order. first (self): (LIKE (ANY-VALUE SELF)) [Method on VECTOR] Not documented. second (self): (LIKE (ANY-VALUE SELF)) [Method on VECTOR] Not documented. third (self): (LIKE (ANY-VALUE SELF)) [Method on VECTOR] Not documented. fourth (self): (LIKE (ANY-VALUE SELF)) [Method on VECTOR] Not documented. fifth (self): (LIKE (ANY-VALUE SELF)) [Method on VECTOR] Not documented. nth (self (position integer)): (LIKE (ANY-VALUE SELF)) [Method on VECTOR] Not documented. last (self): (LIKE (ANY-VALUE SELF)) [Method on VECTOR] Return the last item in the vector self. but-last (self): (ITERATOR OF (LIKE (ANY-VALUE SELF))) [Method on VECTOR] Generate all but the last element of the vector self. length (self): INTEGER [Method on VECTOR] Not documented. member? (self (object OBJECT)): BOOLEAN [Method on VECTOR] Not documented. position (self (object object) (start integer)): integer [Method on VECTOR] Return the position of object within the vector self (counting from zero); or return null if object does not occur within self (uses an eq1? test). If start was supplied as non-'null', only consider the portion starting at start, however, the returned position will always be relative to the entire vector. last-position (self (object object) (end integer)): [Method on VECTOR] Return the position of object within the vector self (counting from zero); or return null if object does not occur within self (uses an eql? test). If end was supplied as non-'null', only consider the portion ending at index end, however, the returned position will always be relative to the entire vector. insert-at (self (offset integer) [Method on VECTOR] (value (LIKE (ANY-VALUE SELF)))):

[Class]

copy (self): (VECTOR OF (LIKE (ANY-VALUE SELF))) [Method on VECTOR] Return a copy of the vector self. clear (self): [Method on VECTOR] Not documented. resize-vector ((self VECTOR) (size INTEGER)): [Function] Change the size of self to size. If size is smaller than the current size of self the vector will be truncated. Otherwise, the internal array of self will be grown to size and unused elements will be initialized to NULL. consify (self): (CONS OF (LIKE (ANY-VALUE SELF))) [Method on VECTOR] Return a list of elements in self. insert-at (self (offset integer) [Method on Extensible-Vector] (value (LIKE (ANY-VALUE SELF)))): Not documented. insert (self (value (LIKE (ANY-VALUE SELF)))) : [Method on Vector-sequence] Append value to the END of the sequence self. Resize the array if necessary. remove (self (value (LIKE (ANY-VALUE SELF)))): [Method on Vector-sequence] VECTOR-SEQUENCE Remove value from the sequence self, and left shift the values after it to close the gap. length (self): INTEGER [Method on Vector-sequence] Not documented.

6.9 Hash Tables

Not documented.

Not documented.

STRING-TO-INTEGER-HASH-TABLE : ABSTRACT-HASH-TABLE

HASH-TABLE : ABSTRACT-HASH-TABLE [Class] Not documented. any-key : OBJECT [Class Parameter of] Not documented. any-value : OBJECT [Class Parameter of] Not documented. STRING-HASH-TABLE : ABSTRACT-HASH-TABLE [Class] Not documented. any-key : STRING [Class Parameter of] Not documented. any-value : OBJECT [Class Parameter of]

any-key : STRING [Class Parameter of] Not documented. [Class Parameter of] any-value : INTEGER Not documented. INTEGER-HASH-TABLE : ABSTRACT-HASH-TABLE [Class] Not documented. any-key: INTEGER [Class Parameter of] Not documented. [Class Parameter of] any-value : OBJECT Not documented. [Class] FLOAT-HASH-TABLE: ABSTRACT-HASH-TABLE Not documented. any-key : FLOAT [Class Parameter of] Not documented. [Class Parameter of] any-value : OBJECT Not documented. lookup (self (key (like (any-key self)))) : (like [Method on HASH-TABLE] (ANY-VALUE SELF)) Not documented. insert-at (self (key (LIKE (ANY-KEY SELF))) [Method on HASH-TABLE] (value (LIKE (ANY-VALUE SELF)))): Not documented. remove-at (self (key (LIKE (ANY-KEY SELF)))): [Method on HASH-TABLE] Not documented. lookup (self (key string)) : (LIKE (ANY-VALUE [Method on STRING-HASH-TABLE] SELF)) Not documented. [Method on STRING-HASH-TABLE] insert-at (self (key STRING) (value OBJECT)) : Not documented. remove-at (self (key STRING)): [Method on STRING-HASH-TABLE] Not documented. lookup (self (key STRING)): [Method on STRING-TO-INTEGER-HASH-TABLE] INTEGER Not documented. insert-at (self (key STRING) [Method on STRING-TO-INTEGER-HASH-TABLE] (value integer)): Not documented.

lookup (self (key integer)): (Like (any-value [Method on integer-hash-table] self))

Not documented.

insert-at (self (key integer) (value object)) [Method on integer-hash-table]

Not documented.

insert-at (self (key FLOAT) (value OBJECT)): [Method on FLOAT-HASH-TABLE] Not documented.

STELLA provides its own implementation of hash tables for cases where language-native implementations are not available, or where additional features are needed.

STELLA-HASH-TABLE : ABSTRACT-HASH-TABLE

[Class]

Not documented.

any-key : OBJECT

[Class Parameter of]

Not documented.

any-value : OBJECT

[Class Parameter of]

Not documented.

the-table : (ARRAY SIZE () OF KV-CONS)

[Slot of]

Not documented.

size : INTEGER

[Slot of]

Not documented.

initial-size : INTEGER

[Slot of]

If supplied, the initial hash table will be sized to hold at least that many elements.

free-elements : INTEGER

[Slot of]

Not documented.

equal-test? : BOOLEAN

[Slot of]

If true use equal? as the equality test and equal-hash-code as the hash function, otherwise, use eql? and hash-code (the default).

lookup (self (key (LIKE (ANY-KEY SELF)))) : [Method on STELLA-HASH-TABLE] (LIKE (ANY-VALUE SELF))

Lookup the entry identified by key in self and return its value, or NULL if no such entry exists. Uses an eq1? test by default or equal? if equal-test? of self is TRUE.

insert-at (self (key (LIKE (ANY-KEY SELF))) [Method on STELLA-HASH-TABLE] (value (LIKE (ANY-VALUE SELF)))) :

Set the value of the entry identified by key in self to value or add a new entry if no entry with key exists yet. Uses an eql? test by default or equal? if equal-test? of self is TRUE.

remove-at (self (key (LIKE (ANY-KEY SELF)))): [Method on STELLA-HASH-TABLE] Remove the entry identified by key from self. Uses an eql? test by default or equal? if equal-test? of self is TRUE.

length (self): INTEGER

[Method on Stella-Hash-Table]

Return the number of entries in self.

empty? (self): BOOLEAN

[Method on STELLA-HASH-TABLE]

Return TRUE if self has zero entries.

non-empty? (self): BOOLEAN

[Method on STELLA-HASH-TABLE]

Return TRUE if self has at least 1 entry.

copy (self): (LIKE SELF)

[Method on Stella-Hash-Table]

Return a copy of the hash table *self*. The bucket table and buckets are freshly allocated, however, the keys and values of entries are not copied themselves (similar to what we do for lists, etc.).

clear (self):

[Method on Stella-Hash-Table]

Remove all entries from self. This will result in a re-initialization of the table upon the first insertion into self.

consify (self) : (CONS OF CONS)

[Method on STELLA-HASH-TABLE]

Collect all entries of self into a cons list of (<key> <value>) pairs and return the result.

object-equal? (x (y OBJECT)) : BOOLEAN

[Method on Stella-Hash-Table]

Return TRUE if x and y represent the same set of key/value pairs.

equal-hash-code (self): INTEGER

[Method on STELLA-HASH-TABLE]

Return an equal? hash code for self. Note that this is O(N) in the number of entries of self.

allocate-iterator (self):

[Method on STELLA-HASH-TABLE]

(STELLA-HASH-TABLE-ITERATOR OF (LIKE (ANY-KEY SELF)) (LIKE

(ANY-VALUE SELF)))

Allocate an iterator for self.

Hashing objects into STELLA hash tables is accomplished via hash-code and equal-hash-code methods. These methods are implemented for all built-in STELLA types but are user extensible for cases where special functionality on user-defined objects is needed. Defining new hash-code methods should only be necessary if new wrapper types are defined, since for all types descending from STANDARD-OBJECT the built-in method should be adequate.

object-hash-code ((self object)) : INTEGER

[Function]

Return a hash code for self (can be negative). Two objects that are eq? are guaranteed to generate the same hash code. Two objects that are not eq? do not necessarily generate different hash codes. Similar to hash-code but always hashes on the address of self even if it is a wrapper.

hash-code (self): INTEGER

[Method on OBJECT]

Return a hash code for *self* (can be negative). Two objects that are eq1? are guaranteed to generate the same hash code. Two objects that are not eq1? do not necessarily generate different hash codes.

hash-code (self): INTEGER

[Method on STANDARD-OBJECT]

Not documented.

hash-code (self): INTEGER
Not documented.

[Method on STRING-WRAPPER]

hash-code (self): INTEGER Not documented.

[Method on Integer-wrapper]

hash-code (self): INTEGER Not documented.

[Method on FLOAT-WRAPPER]

hash-code (self): INTEGER Not documented.

[Method on CHARACTER-WRAPPER]

hash-code (self): INTEGER
Not documented.

[Method on BOOLEAN-WRAPPER]

hash-code (self): INTEGER Not documented.

[Method on STRING]

hash-code (self): INTEGER Not documented.

[Method on INTEGER]

hash-code (self): INTEGER Not documented.

[Method on FLOAT]

hash-code (self): INTEGER
Not documented.

[Method on CHARACTER]

equal-hash-code (self): INTEGER

[Method on OBJECT]

Return a hash code for *self* (can be negative). Two objects that are equal? are guaranteed to generate the same hash code (provided, that writers of object-equal? methods also implemented the appropriate equal-hash-code method). Two objects that are not equal?do not necessarily generate different hash codes.

The following low-level utilities are available to implement specialized hashing schemes or for defining new versions of equal-hash-code.

hashmod ((code integer) (size integer)): integer

[Function]

Map the hash code code onto a bucket index for a hash table of size (i.e., onto the interval [0..size-1]. This is just like rem for positive hash codes but also works for negative hash codes by mapping those onto a positive number first. Note, that the sign conversion mapping is not equivalent to calling the abs function (it simply masks the sign bit for speed) and therefore really only makes sense for hash codes.

rotate-hash-code ((arg INTEGER)): INTEGER

[Function]

Rotate arg to the right by 1 position. This means shift arg to the right by one and feed in args bit zero from the left. In Lisp the result will stay in positive FIXNUM range. In C++ and Java this might return a negative value which might be equal to NULL-INTEGER. Important: to make this inlinable, it must be called with an atom (i.e., constant or variable) as its argument. This function is primarily useful for hashing sequences of items where the hash code should take the sequential order of elements into account (e.g., lists).

6.10 Key Value Maps

KEY-VALUE-MAP is a full-featured dictionary class that supports eq1? or extensible equal? equality tests, O(1) access operations even for large numbers of entries by using a hash table, light-weight KV-CONS representation for small tables and iteration even if the dictionary is represented by a hash table (note that in STELLA we cannot iterate over regular HASH-TABLE's, since native Lisp hash tables do not allow us to implement a hash table iterator). Since large KEY-VALUE-MAP's are implemented via STELLA-HASH-TABLE's, we can support iteration.

KEY-VALUE-MAP : DICTIONARY

[Class]

Full-featured dictionary class that supports eq1? or equal? equality tests, O(1) access operations even for large numbers of entries by using a hash table, light-weight KV-CONS representation for small tables and iteration even if the dictionary is represented by a hash table.

the-map : OBJECT

[Slot of]

Not documented.

equal-test? : BOOLEAN

[Slot of]

If true use equal? as the equality test (and equal-hash-code as the hash function), otherwise, use eql? (and hash-code) (the default).

initial-size : INTEGER

[Slot of]

If supplied, the initial table will be sized to hold at least that many elements.

crossover-point : INTEGER

[Slot of]

Not documented.

lookup (golf (kov (LIVE (ANV V

lookup (self (key (LIKE (ANY-KEY SELF)))) : (LIKE [Method on KEY-VALUE-MAP] (ANY-VALUE SELF))

Lookup the entry identified by key in self and return its value, or NULL if no such entry exists. Uses an eql? test by default or equal? if equal-test? of self is TRUE.

```
insert-at (self (key (LIKE (ANY-KEY SELF))) [Method on KEY-VALUE-MAP] (value (LIKE (ANY-VALUE SELF)))):
```

Set the value of the entry identified by key in self to value or add a new entry if no entry with key exists yet. Uses an eql? test by default or equal? if equal-test? of self is TRUE.

remove-at (self (key (LIKE (ANY-KEY SELF)))): [Method on KEY-VALUE-MAP] Remove the entry identified by key from self. Uses an eq1? test by default or equal? if equal-test? of self is TRUE.

length (self): INTEGER
Return the number of entries in self.

[Method on KEY-VALUE-MAP]

rectain the number of entires in sen

empty? (self): BOOLEAN

[Method on KEY-VALUE-MAP]

Return TRUE if self has zero entries.

non-empty? (self): BOOLEAN

[Method on KEY-VALUE-MAP]

Return TRUE if self has at least 1 entry.

copy (self): (LIKE SELF)

[Method on KEY-VALUE-MAP]

Return a copy of the map self. All entries are freshly allocated, however, the keys and values of entries are not copied themselves (similar to what we do for lists, etc.).

clear (self):

[Method on KEY-VALUE-MAP]

Reset self to have zero entries.

allocate-iterator (self): (DICTIONARY-ITERATOR [Method on KEY-VALUE-MAP]
OF (LIKE (ANY-KEY SELF)) (LIKE (ANY-VALUE SELF)))

Allocate an iterator for *self*. The only modifying operations allowed during iteration are removal of the current element or changing its value. All other removal or insertion operations might lead to corruption or undefined results.

consify (self): CONS

[Method on KEY-VALUE-MAP]

Collect all entries of self into a cons list of (<key> <value>) pairs and return the result.

object-equal? (x (y OBJECT)): BOOLEAN [Method on KEY-VALUE-MAP] Return TRUE if x and y represent the same set of key/value pairs.

equal-hash-code (self) : INTEGER

[Method on KEY-VALUE-MAP]

Return an equal? hash code for self. Note that this is O(N) in the number of entries of self.

6.11 Hash Sets

HASH-SET is a full-featured set class that supports eq1? or extensible equal? equality tests, O(1) insert and member? operations, O(N) intersection etc. operations even for large numbers of entries by using a STELLA hash table, light-weight KV-CONS representation for small sets and iteration even if the set is represented by a hash table. The only minor drawback right now is that we waste one value slot per entry, since we piggy-back off KEY-VALUE-MAP's, however, that wastes at most 25% space.

HASH-SET : KEY-VALUE-MAP, SET-MIXIN

[Class]

Full-featured set class that supports eq1? or equal? equality tests, O(1) insert and member? operations & O(N) intersection etc. operations even for large numbers of entries by using a hash table, light-weight KV-CONS representation for small sets

and iteration even if the set is represented by a hash table. The only minor drawback right now is that this wastes a value slot per entry, since we piggy-back off KEY-VALUE-MAP's, however, that wastes at most 25% space.

hash-set (&rest (values OBJECT)): HASH-SET Return an eq1? HASH-SET containing values. [Function]

- member? (self (object OBJECT)): BOOLEAN [Method on HASH-SET] Return TRUE iff object is a member of the set self. Uses an eql? test by default or equal? if equal-test? of self is TRUE.
- insert (self (value (LIKE (ANY-VALUE SELF)))): [Method on HASH-SET] Add value to the set self unless it is already a member. Uses an eq1? test by default or equal? if equal-test? of self is TRUE.
- remove (self (value (LIKE (ANY-VALUE SELF)))): (LIKE SELF) [Method on HASH-SET] Destructively remove value from the set self if it is a member and return self. Uses an eql? test by default or equal? if equal-test? of self is TRUE.
- remove-if (self (test? function-code)): (LIKE SELF) [Method on HASH-SET]

 Destructively remove all elements of the set self for which test? evaluates to TRUE.

 test? takes a single argument of type OBJECT and returns TRUE or FALSE. Returns self.
- pop (self): (LIKE (ANY-VALUE SELF)) [Method on HASH-SET] Remove and return an arbitrary element of the set self. Return NULL if the set is empty. Performance note: for large sets implemented via hash tables it takes O(N) to empty out the set with repeated calls to pop, since the emptier the table gets, the longer it takes to find an element. Therefore, it is usually better to use iteration with embedded removals for such cases.
- substitute (self (new OBJECT) (old OBJECT)): (LIKE SELF) [Method on HASH-SET] Destructively replace old with new in the set self unless new is already a member. Uses an eq1? test by default or equal? if equal-test? of self is TRUE.
- copy (self): (LIKE SELF) [Method on HASH-SET]
 Return a copy of the set self. All entries are freshly allocated, however, the values are not copied themselves (similar to what we do for lists, etc.).
- consify (self): (CONS OF (LIKE (ANY-VALUE SELF))) [Method on HASH-SET] Collect all entries of self into a cons list and return the result.
- Return true if every element of self also occurs in otherSet. Uses an eql? test by default or equal? if equal-test? of self is TRUE.
- equivalent-sets? (self (otherSet hash-set)): BOOLEAN [Method on hash-set]
 Return true if every element of self occurs in otherSet and vice versa. Uses an eq1?
 test by default or equal? if equal-test? of self is TRUE.

- intersection (self (otherSet Hash-set)): Hash-set [Method on Hash-set] Return the set intersection of self and otherSet as a new set. Uses an eql? test by default or equal? if equal-test? of self is TRUE.
- union (self (otherSet HASH-SET)): HASH-SET [Method on HASH-SET] Return the set union of self and otherSet as a new set. Uses an eq1? test by default or equal? if equal-test? of self is TRUE.
- difference (self (otherSet HASH-SET)): HASH-SET [Method on HASH-SET]
 Return the set difference of self and otherSet as a new set (i.e., all elements that are in self but not in otherSet). Uses an eql? test by default or equal? if equal-test? of self is TRUE.
- subtract (self (otherSet hash-set)): hash-set [Method on hash-set] Return the set difference of self and otherSet by destructively removing elements from self that also occur in otherSet. Uses an eql? test by default or equal? if equal-test? of self is TRUE.
- object-equal? (x (y OBJECT)): BOOLEAN [Method on HASH-SET] Return TRUE iff sets x and y are HASH-SET's with equivalent members. Uses an eql? test by default or equal? if equal-test? of self is TRUE. This is equivalent to calling equivalent-sets?.
- equal-hash-code (self): INTEGER [Method on HASH-SET] Return an equal? hash code for self. Note that this is O(N) in the number of elements of self.

6.12 Iterators

- empty? (self): BOOLEAN [Method on ITERATOR]
 Return TRUE if the sequence represented by self has no elements. Side-effect free.
- member? (self (value OBJECT)): BOOLEAN [Method on ITERATOR]
 Iterate over values of self, returning TRUE if one of them is eql to 'value.
- length (self): INTEGER [Method on ABSTRACT-ITERATOR]
 Iterate over self, and count how many items there are. Bad idea if self iterates over an infinite collection, since in that case it will run forever.'
- pop (self): (LIKE (ANY-VALUE SELF)) [Method on ITERATOR] Return the first item of the sequence represented by self, or NULL if it is empty. Destructively uses up the first iteration element.
- advance (self (n integer)): (Like self) [Method on iterator] Return self after skipping over the first n elements in the (remainder of the) iteration.
- concatenate (iterator1 (iterator2 iterator8) [Method on iterator8] &rest (otherIterators iterator8)): All-Purpose-iterator Return an iterator that first generates all values of iterator1, then those of iterator2, and then those of all otherIterators. The generated values can be filtered by supplying a filter function to the resulting iterator.

consify (self): (CONS OF (LIKE (ANY-VALUE SELF))) [Method on ITERATOR]
Return a list of elements generated by self.

next? (self): BOOLEAN [Method on ALL-PURPOSE-ITERATOR]
Apply the stored next? function to self.

6.13 Symbols

lookup-symbol ((name STRING)): SYMBOL [Function]
Return the first symbol with name visible from the current module.

intern-symbol ((name STRING)): SYMBOL [Function]
Return a newly-created or existing symbol with name name.

unintern-symbol ((self SYMBOL)): [Function]
Remove self from its home module and the symbol table.

lookup-symbol-in-module ((name STRING) (module MODULE) [Function] (local? BOOLEAN)): SYMBOL

Return the first symbol with name visible from module. If local? only consider

intern-symbol-in-module ((name STRING) (module MODULE) [Function] (local? BOOLEAN)): SYMBOL

symbols directly interned in module. If module is null, use *MODULE* instead.

Look for a symbol named *name* in *module* (if *local?* do not consider inherited modules). If none exists, intern it locally in *module*. Return the existing or newly-created symbol.

Return a newly-created or existing symbol with name newName which is interned in the same module as baseSymbol.

visible-symbol? ((self SYMBOL)): BOOLEAN [Function]

Return true if self is visible from the current module.

lookup-visible-symbols-in-module ((name STRING) [Function] (module MODULE) (enforceShadowing? BOOLEAN)): (CONS OF SYMBOL)
Return the list of symbols with name visible from module. More specific symbols (relative to the module precedence order defined by visible-modules) come earlier in the list. If module is null, start from *MODULE* instead. If enforceShadowing? is true, do not return any symbols that are shadowed due to some :SHADOW declaration.

import-symbol ((symbol symbol) (module module)): symbol. [Function] Import symbol into module and return the imported symbol. Signal an error if a different symbol with the same name already exists locally in module. Any symbol with the same name visible in module by inheritance will be shadowed by the newly imported symbol.

safe-import-symbol ((symbol symbol) (module Module)): symbol [Function] Safe version of import-symbol (which see). Only imports symbol if no symbol with that name is currently interned or visible in module. Returns symbol if it was imported or the conflicting symbol in module otherwise.

lookup-surrogate ((name STRING)) : SURROGATE

[Function]

Return the first surrogate with name visible from the current module.

intern-surrogate ((name STRING)) : SURROGATE

[Function]

Return a newly-created or existing surrogate with name name.

unintern-surrogate ((self SURROGATE)):

[Function]

Remove self from its home module and the surrogate table.

lookup-surrogate-in-module ((name STRING) (module MODULE) (local? BOOLEAN)): SURROGATE

[Function]

Return the first surrogate with name visible from module. If local? only consider surrogates directly interned in module. If module is null, use *MODULE* instead.

[Function]

Look for a symbol named name in module (if local? do not consider inherited modules). If none exists, intern it locally in module. Return the existing or newly-created symbol.

intern-derived-surrogate ((baseSymbol GENERALIZED-SYMBOL) (newName STRING)): SURROGATE

[Function]

Return a newly-created or existing surrogate with name newName which is interned in the same module as baseSymbol.

visible-surrogate? ((self SURROGATE)) : BOOLEAN

[Function]

Return true if self is visible from the current module.

lookup-visible-surrogates-in-module ((name STRING)

[Function]

(module Module) (enforceShadowing? Boolean)): (Cons of surrogate) Return the list of surrogates with name visible from module. More specific surrogates (relative to the module precedence order defined by visible-modules) come earlier in the list. If module is null, start from *MODULE* instead. If enforceShadowing? is true, do not return any surrogates that are shadowed due to some :SHADOW declaration.

import-surrogate ((surrogate SURROGATE) (module MODULE)): [Function]
SURROGATE

Import surrogate into module and return the imported surrogate. Signal an error if a different surrogate with the same name already exists locally in module. Any surrogate with the same name visible in module by inheritance will be shadowed by the newly imported surrogate.

safe-import-surrogate ((surrogate SURROGATE) (module MODULE)) : [Function]
SURROGATE

Safe version of import-surrogate (which see). Only imports surrogate if no surrogate with that name is currently interned or visible in module. Returns surrogate if it was imported or the conflicting surrogate in module otherwise.

lookup-keyword ((name STRING)) : KEYWORD

[Function]

Return the keyword with name if it exists.

intern-keyword ((name STRING)) : KEYWORD

[Function]

Return a newly-created or existing keyword with name name. Storage note: a COPY of name is stored in the keyword

gensym ((prefix STRING)) : SYMBOL

[Function]

Return a transient symbol with a name beginning with *prefix* and ending with a globally gensym'd integer.

local-gensym ((prefix STRING)): SYMBOL Not documented.

[Function]

symbol-plist ((symbol symbol)) : CONS

[Function]

Return the property list of symbol. The symbol-plist of a symbol can be set with setf. IMPORTANT: Property list are modified destructively, hence, if you supply it as a whole make sure to always supply a modifiable copy, e.g., by using bquote.

symbol-property ((symbol symbol) (key standard-object)): [Function]

Return the property of *symbol* whose key is eq? to key. Symbol properties can be set with setf.

symbol-value ((symbol SYMBOL)) : OBJECT

[Function]

Return the value of *symbol*. Note, that this value is not visible to code that references a variable with the same name as *symbol*. The <code>symbol-value</code> is simply a special property that can always be accessed in constant time. The <code>symbol-value</code> of a symbol can be changed with <code>setf</code>.

symbolize ((surrogate SURROGATE)) : SYMBOL

[Function]

Convert surrogate into a symbol with the same name and module.

6.14 Context and Modules

get-stella-context ((pathName string) (error? boolean)): [Function]

Return the context located at *pathName*, or **null** if no such context exists. If *error*? is **true**, throw an exception if no context is found, otherwise silently return **null**.

clear-context ((self CONTEXT)) :

[Function]

Destroy all objects belonging to self or any of its subcontexts.

within-context ((contextForm OBJECT) &body (body CONS)): OBJECT [Macro] Execute body within the context resulting from contextForm.

```
destroy-context (self):
                                                             [Method on CONTEXT]
     Make the translator happy.
destroy-context (self):
                                                               [Method on STRING]
     Destroy the context self, and recursively destroy all contexts that inherit self.
change-context (context) : CONTEXT
                                                             [Method on Context]
     Change the current context to be the context context.
change-context (contextName) : CONTEXT
                                                               [Method on STRING]
     Change the current context to be the context named contextName.
cc (&rest (name NAME)) : CONTEXT
                                                                     [N-Command]
     Change the current context to the one named name. Return the value of the new
     current context. If no name is supplied, return the pre-existing value of the current
     context. cc is a no-op if the context reference cannot be successfully evaluated.
defmodule ((name NAME) & rest (options OBJECT)):
                                                                     [N-Command]
     Define (or redefine) a module named name. The accepted syntax is:
             (defmodule <module-name>
                [:documentation <docstring>]
                [:includes {<module-name> | (<module-name>*)}]
                [:uses {<module-name> | (<module-name>*)}]
                [:lisp-package <package-name-string>]
                [:java-package <package-specification-string>]
                [:cpp-namespace <namespace-name-string>]
                [: java-catchall-class
                [:api? {TRUE | FALSE}]
                [:case-sensitive? {TRUE | FALSE}]
                [:shadow (<symbol>*)]
                [:java-catchall-class <class-name-string>]
                [<other-options>*])
```

name can be a string or a symbol.

Modules include objects from other modules via two separate mechanisms: (1) they inherit from their parents specified via the :includes option and/or a fully qualified module name, and (2) they inherit from used modules specified via the :uses option. The main difference between the two mechanisms is that inheritance from parents is transitive, while uses-links are only followed one level deep. I.e., a module A that uses B will see all objects of B (and any of B's parents) but not see anything from modules used by B. Another difference is that only objects declared as public can be inherited via uses-links (this is not yet enforced). Note that - contrary to Lisp - there are separate name spaces for classes, functions, and variables. For example, a module could inherit the class CONS from the STELLA module, but shadow the function of the same name.

The above discussion of :includes and :uses semantics keyed on the inheritance/visibility of symbols. The PowerLoom system makes another very important distinction: If a module A is inherited directly or indirectly via :includes specification(s) by a submodule B, then all definitions and facts asserted in A are

visible in B. This is not the cases for :uses; the :uses options does not impact inheritance of propositions at all.

The list of modules specified in the :includes option plus (if supplied) the parent in the path used for *name* become the new module's parents. If no :uses option was supplied, the new module will use the STELLA module by default, otherwise, it will use the set of specified modules.

If :case-sensitive? is supplied as TRUE, symbols in the module will be interned case-sensitively, otherwise (the default), they will be converted to uppercase before they get interned. That means that any reference from inside a case-sensitive module to a non-case-sensitive module will have to use uppercase names for symbols in the non-case-sensitive module. The standard system modules are all NOT case sensitive.

Modules can shadow definitions of functions and classes inherited from parents or used modules. Shadowing is done automatically, but generates a warning unless the shadowed type or function name is listed in the :shadow option of the module definition .

Examples:

```
(defmodule "PL-KERNEL/PL-USER"
  :uses ("LOGIC" "STELLA")
  :package "PL-USER")
```

(defmodule PL-USER/GENEALOGY)

The remaining options are relevant only for modules that contain STELLA code. Modules used only to contain knowledge base definitions and assertions have no use for them:

The keywords:lisp-package,:java-package, and:cpp-package specify the name of a native package or name space in which symbols of the module should be allocated when they get translated into one of Lisp, Java, or C++. By default, Lisp symbols are allocated in the STELLA package, and C++ names are translated without any prefixes. The rules that the STELLA translator uses to attach translated Java objects to classes and packages are somewhat complex. Use: java-package option to specify a list of package names (separated by periods) that prefix the Java object in this module. Use: java-catchall-class to specify the name of the Java class to contain all global & special variables, parameter-less functions and functions defined on arguments that are not classes in the current module. The default value will be the name of the module.

When set to TRUE, the :api? option tells the PowerLoom User Manual generator that all functions defined in this module should be included in the API section. Additionally, the Java translator makes all API functions synchronized.

```
get-stella-module ((pathName STRING) (error? BOOLEAN)): [Function]
MODULE
```

Return the module located at *pathName*, or null if no such module exists. The search looks at ancestors and top-most (cardinal) modules. If *error*? is true, throw an exception if no module is found.

```
find-or-create-module ((pathname STRING)): MODULE [Function]
Return a module located at pathname if one exists, otherwise create one
```

clear-module (&rest (name NAME)) :

[N-Command]

Destroy all objects belonging to module *name* or any of its children. If no *name* is supplied, the current module will be cleared after confirming with the user. Important modules such as STELLA are protected against accidental clearing.

destroy-module ((self MODULE)) :

[Function]

Destroy the module self, and recursively destroy all contexts that inherit self.

destroy-context (self):

[Method on MODULE]

Destroy the context self, and recursively destroy all contexts that inherit self.

visible-modules ((from MODULE)) : (CONS OF MODULE)

[Function]

Return a list of all modules visible from module from (or *module* if from is NULL. The generated modules are generated from most to least-specific and will start with the module from.

within-module ((moduleForm OBJECT) &body (body CONS)): OBJECT [Macro] Execute body within the module resulting from moduleForm. *module* is an acceptable moduleForm. It will locally rebind *module* and *context* and shield the outer bindings from changes.

in-module ((name NAME)) : MODULE

[N-Command]

Change the current module to the module named name.

change-module (module): MODULE

[Method on MODULE]

Change the current module to be the module module.

change-module (moduleName) : MODULE

[Method on STRING]

Change the current module to be the module named moduleName.

create-world ((parentContext CONTEXT) (name STRING)): WORLD [Function] Create a new world below the world or module parentContext. Optionally, specify a name.

push-world () : WORLD

[Command]

Spawn a new world that is a child of the current context, and change the current context to the new world.

pop-world () : CONTEXT

[Command]

Destroy the current world and change the current context to be its parent. Return the current context. Nothing happens if there is no current world.

destroy-context (self):

[Method on WORLD]

Destroy the context self, and recursively destroy all contexts that inherit self.

within-world ((worldForm OBJECT) &body (body CONS)): OBJECT [Macro] Execute body within the world resulting from worldForm.

6.15 Input and Output

read-s-expression ((stream INPUT-STREAM)) : OBJECT BOOLEAN [Function] Read one STELLA s-expression from stream and return the result. Return true as the second value on EOF.

read-s-expression-from-string ((string STRING)) : OBJECT [Function] Read one STELLA s-expression from string and return the result.

read-line ((stream INPUT-STREAM)) : STRING

Read one line from stream and return the result. This differs from native-read-line in that it is not platform-dependent. It recognizes any of the three common line ending formats: CR, LF, CR-LF in any combination. It is not as fast as native-read-line, however.

read-character ((inputStream input-stream)) : CHARACTER [Function]

Read one character from inputStream and return the result. Return true as the second value on EOF.

unread-character ((ch Character) (inputStream input-stream)): [Function] Unread ch from inputStream. Signal an error if ch was not the last character read.

y-or-n? ((message STRING)): BOOLEAN

[Function]

[Function]

Read a line of input from STANDARD-INPUT and return true if the input was y or false if the input was n. Loop until either y or n was entered. If message is non-'null' prompt with it before the input is read. See also special variable *USER-QUERY-ACTION*.

yes-or-no? ((message STRING)) : BOOLEAN [Function] Read a line of input from STANDARD-INPUT and return true if the input was yes or false if the input was no. Loop until either yes or no was entered. If message is non-'null' prompt with it before the input is read. See also special variable *USER-QUERY-ACTION*.

flush-output ((self OUTPUT-STREAM)): [Function] Flush all buffered output of self.

6.16 Files

open-input-file ((fileName STRING) & rest (options KEYWORD)): [Function] FILE-INPUT-STREAM

Open file fileName for input and return the resulting input stream. By default signal an error if the file does not exist. The only legal option so far is :IF-NOT-EXISTS (or : IF-NOT-EXISTS-ACTION) which specifies what to do in case the file does not exist. If its value is :ERROR then an error will be signaled. If it is :ABORT or :PROBE the opening operation will be aborted and NULL will be returned.

open-output-file ((fileName STRING) &rest (options KEYWORD)): [Function]
FILE-OUTPUT-STREAM

Open file fileName for output and return the resulting output stream. By default the file will be created or overwritten if it already exists. If :IF-EXISTS (or :IF-EXISTS-ACTION) is one of the options its value specifies what to do in case the file already exists. If the value is :SUPERSEDE the pre-existing file will be overwritten. If the value is :APPEND the preexisting file will be appended to (if the file did not yet exist the file will simply be created). If the value is :ERROR then an error will be signaled. If it is :ABORT or :PROBE the opening operation will be aborted and NULL will be returned. If :IF-NOT-EXISTS (or :IF-NOT-EXISTS-ACTION) is one of the options its value specifies what to do in case the file does not already exist. If the value is :CREATE, the file will simply be created. If the value is :CREATE-PATH the file will be created plus any non-existing directories in the directory path of fileName will also be created. If the value is :ERROR then an error will be signaled. If it is :ABORT or :PROBE the opening operation will be aborted and NULL will be returned.

close-stream (($self \, {
m STREAM}$)) :

[Function]

Close the stream self.

close-all-files ():

[Function]

Close all currently open file streams. Use for emergencies or for cleanup.

- with-input-file ((binding cons) &body (body cons)): OBJECT [Macro] Sets up an unwind-protected form which opens a file for input and closes it afterwards. The stream for reading is bound to the variable provided in the macro form. Syntax is (WITH-INPUT-FILE (var filename options*) body+) where options can be any that are legal for open-input-file (which see).
- with-output-file ((binding cons) &body (body cons)): OBJECT [Macro] Sets up an unwind-protected form which opens a file for output and closes it afterwards. The stream for writing is bound to the variable provided in the macro form. Syntax is (WITH-OUTPUT-FILE (var filename options*) body+) where options can be any that are legal for open-output-file (which see).
- probe-file? ((fileName FILE-NAME)): BOOLEAN [Function] Return true if file fileName exists. Note that this does not necessarily mean that the file can also be read. IMPORTANT Java idiosyncrasy: if file foo/bar exists and is not a directory, Java will also say foo/bar/ exists, which is different behavior than in Lisp and C++. For this reason, make sure to always use probe-directory? to test whether a directory exists.
- file-write-date ((fileName FILE-NAME)): CALENDAR-DATE [Function] Return the time at which file fileName was last modified or NULL if that cannot be determined.
- file-length ((fileName FILE-NAME)): LONG-INTEGER [Function] Return the length of file fileName in bytes or NULL if that cannot be determined.
- copy-file ((fromFile file-NAME) (toFile file-NAME)): [Function] Copy file fromFile to file toFile, clobbering any data already in toFile.

delete-file ((fileName FILE-NAME)) :
Delete the file fileName.

[Function]

rename-file ((fromFile FILE-NAME) (toFile FILE-NAME)):

[Function]

Rename the file from File to to File.

[Function]

Return a file name of the form prefix>NNNNNN<suffix> which is guaranteed to not refer to any existing file. A null prefix defaults to tmpfile, a null suffix defaults to the empty string. The number portion NNNNNN will correpond to a random number between 0 and 999999. If no qualifying filename can be found after 100 attempts, NULL will be returned. Note that it is possible due to multi-threading or processing that the generated filename becomes used by another thread or OS process. If necessary, this case can be handled by the caller.

directory-file-name ((directory FILE-NAME)) : FILE-NAME

[Function]

Return directory as a file name, i.e., without a terminating directory separator.

directory-parent-directory ((directory FILE-NAME)

[Function]

(level integer)) : file-name

Return the *level*-th parent directory component of *directory* including the final directory separator, or the empty string if *directory* does not have that many parents.

file-name-as-directory ((file FILE-NAME)) : FILE-NAME

[Function]

Return file interpreted as a directory, i.e., with a terminating directory separator. If file is the empty string simply return the empty string, i.e., interpret it as the current directory instead of the root directory.

file-name-directory ((file FILE-NAME)) : FILE-NAME

[Function]

Return the directory component of *file* including the final directory separator or the empty string if *file* does not include a directory. Note that for purposes of this function, a logical host is considered part of the directory portion of *file*

- file-name-without-directory ((file FILE-NAME)): FILE-NAME [Function] Return the file name portion of file by removing any directory and logical host components.
- file-name-without-extension ((file FILE-NAME)): FILE-NAME [Function] Remove files extension (or type) if there is any and return the result.
- file-extension ((file FILE-NAME)): STRING [Function]
 Return files extension (or type) if it has any including the separator character.
- file-base-name ((file FILE-NAME)): FILE-NAME [Function]
 Remove files directory (including logical host) and extension components and return the result.
- absolute-pathname? ((pathname STRING)): BOOLEAN [Function] Not documented.

logical-host? ((host STRING)): BOOLEAN

[Function]

Not documented.

 ${\tt logical-pathname?}\ ((pathname\ {\tt STRING})): {\tt BOOLEAN}$

[Function]

Not documented.

 ${\tt translate-logical-pathname\ ((\it pathname\ {\tt STRING})): STRING})): {\tt STRING}$

[Function]

Not documented.

directory-separator () : CHARACTER

[Function]

Not documented.

directory-separator-string () : STRING

[Function]

Not documented.

6.17 Dates and Times

get-current-date-time () : INTEGER INTEGER INTEGER KEYWORD

[Function]

INTEGER INTEGER INTEGER

Returns the current time in UTC as multiple values of year month day day-of-week hour minute second millisecond. Currently millisecond will always be zero (even in Java where it is technically available).

get-local-time-zone () : FLOAT

[Function]

Returns the current time zone offset from UTC as a float, considering the effects of daylight savings time.

make-current-date-time () : CALENDAR-DATE

[Function]

Create a calendar date with current time and date.

make-date-time ((year INTEGER) (month INTEGER) (day INTEGER) [Function] (hour INTEGER) (minute INTEGER) (second INTEGER) (millis INTEGER) (timezone FLOAT)): CALENDAR-DATE

Create a calendar date with the specified components. *year* must be the complete year (i.e., a year of 98 is 98 A.D in the 1st century). *timezone* is a real number in the range -12.0 to +14.0 where UTC is zone 0.0; The number is the number of hours to add to UTC to arrive at local time.

parse-date-time ((date-time-string STRING) (start INTEGER) [Function]

(end integer) (error-on-mismatch? Boolean)): Decoded-date-time

Tries very hard to make sense out of the argument *date-time-string* and returns a time structure if successful. If not, it returns null. If *error-on-mismatch?* is true, parse-date-time will signal an error instead of returning null. Default values are 00:00:00 local time on the current date

decode-calendar-date (date (timezone FLOAT)): [Method on CALENDAR-DATE]

DECODED-DATE-TIME

Returns a decoded time object for date interpreted in timezone is the number of hours added to UTC to get local time. It is in the range -12.0 to +14.0 where UTC is zone 0.0

encode-calendar-date (time-structure): [Method on DECODED-DATE-TIME]

CALENDAR-DATE

Returns a calendar date object for time-structure.

calendar-date-to-string

[???]

Not yet implemented.

string-to-calendar-date ((input STRING)): CALENDAR-DATE [Function]
Returns a calendar date object representing the date and time parsed from the input

string. If no valid parse is found, null is returned.

[???]

relative-date-to-string Not yet implemented.

compute-calendar-date ((julian-day integer)): integer integer [Function]
INTEGER KEYWORD

Returns the YEAR, MONTH, DAY, DAY-OF-WEEK on which the given julian-day begins at noon.

compute-day-of-week ((yyyy INTEGER) (mm INTEGER) (dd INTEGER)) [Function]
: KEYWORD

Returns the day of the week for yyyy-mm-dd.

compute-day-of-week-julian ((julian-day INTEGER)): KEYWORD [Function]
Returns the day of the week for julian-day

compute-julian-day ((yyyy INTEGER) (mm INTEGER) (dd INTEGER)): [Function]
INTEGER

Returns the Julian day that starts at noon on yyyy-mm-dd. yyyy is the year. mm is the month. dd is the day of month. Negative years are B.C. Remember there is no year zero.

compute-next-moon-phase ((n integer) (phase keyword)): [Function] integer float

Returns the Julian Day and fraction of day of the Nth occurence since January 1, 1900 of moon PHASE. PHASE is one of :NEW-MOON, :FIRST-QUARTER, :FULL-MOON, :LAST-QUARTER

decode-time-in-millis ((time integer)): integer integer [Function]
INTEGER INTEGER

Returns multiple values of hours, minutes, seconds, milliseconds for time specified in milliseconds.

julian-day-to-modified-julian-day ((julian-day INTEGER)): [Function]
INTEGER

Returns the modified Julian day during which julian-daystarts at noon.

modified-julian-day-to-julian-day

[Function]

((modified-julian-day integer)): integer

Returns the modified Julian day during which julian-daystarts at noon.

time-add ((t1 DATE-TIME-OBJECT) (t2 DATE-TIME-OBJECT)): [Function]

Add t1 to t2. If one of t1 or t2 is a calendar date, then the result is a calendar date. If both t1 and t2 are relative dates, then the result is a relative date. t1 and t2 cannot both be calendar dates.

- time-divide ((t1 TIME-DURATION) (t2 OBJECT)): OBJECT [Function] Divides the relative date t1 by t2. t2 must be either a relative date or a wrapped number. If t2 is a relative date, then the return value will be a wrapped float. If t2 is a wrapped number, then the reutrn value will be a relative date.
- time-multiply ((t1 OBJECT) (t2 OBJECT)): TIME-DURATION [Function] Multiplies a relative date by a wrapped number. One of t1 or t2 must be a relative date and the other a wrapped number.
- time-subtract ((t1 date-time-object) (t2 date-time-object)): [Function]

Subtract t2 from t1. If t1 is a calendar date, then t2 can be either a calendar date (in which case the return value is a relative date) or it can be a relative date (in which case the return value is a calendar date). If t1 is a relative date, then t2 must also be a relative date and a relative date is returned.

get-ticktock () : TICKTOCK

[Function]

Return the current CPU time. If the current OS/Language combination does not support measuring of CPU time, return real time instead. Use ticktock-difference to measure the time difference between values returned by this function. This is an attempt to provide some platform independent support to measure (at least approximately) consumed CPU time.

ticktock-difference ((t1 TICKTOCK) (t2 TICKTOCK)): FLOAT [Function] The difference in two TICKTOCK time values in seconds where t1 is the earlier time. The resolution is implementation dependent but will normally be some fractional value of a second.

ticktock-resolution (): FLOAT

[Function]

The minimum theoretically detectable resolution of the difference in two TICKTOCK time values in seconds. This resolution is implementation dependent. It may also not be realizable in practice, since the timing grain size may be larger than this resolution.

sleep ((seconds FLOAT)):

[Function]

The program will sleep for the indicated number of seconds. Fractional values are allowed, but the results are implementation dependent: Common Lisp uses the fractions natively, Java with a resolution of 0.001, and C++ can only use integral values.

6.18 XML Support

make-xml-element ((name STRING) (namespace-name STRING) [Function] (namespace STRING)): XML-ELEMENT

Creates and interns an XML element object name using namespace-name to refer to namespace. If namespace is null, then the element will be interned in the null namespace namespace must otherwise be a URI.

make-xml-global-attribute ((name STRING)

[Function]

(namespace-name STRING) (namespace STRING)): XML-GLOBAL-ATTRIBUTE Creates and interns an XML global attribute object with name using namespace-name to refer to namespace. namespacemust be a URI.

make-xml-local-attribute ((name STRING)

[Function]

 $(element \ \text{XML-ELEMENT})): \ \text{XML-LOCAL-ATTRIBUTE}$

Make an XML-LOCAL-ATTRIBUTE named name associated with element

get-xml-tag ((expression cons)) : XML-ELEMENT

[Function]

Return the XML tag object of an XML expression.

get-xml-attributes ((expression cons)) : cons

[Function]

Return the list of attributes of an XML expression (may be empty).

get-xml-content ((expression cons)) : cons

[Function]

Return the list of content elements of an XML expression (may be empty).

get-xml-cdata-content ((form CONS)) : STRING

[Function]

Return the CDATA content of a CDATA form. Does NOT make sure that form actually is a CDATA form, so bad things can happen if it is given wrong input.

xml-declaration? ((item OBJECT)) : BOOLEAN

[Function]

Return true if item is an XML declaration object

xml-element? ((item OBJECT)) : BOOLEAN

[Function]

Return true if item is an XML element object

xml-attribute? ((item OBJECT)) : BOOLEAN

[Function]

Return true if item is an XML attribute object

xml-cdata? ((item object)) : BOOLEAN

[Function]

Return true if item is an XML CDATA tag object

xml-cdata-form? ((form OBJECT)) : BOOLEAN

[Function]

Return true if form is a CONS headed by a CDATA tag

xml-element-match? (tag (name STRING)

[Method on XML-ELEMENT]

(namespace string)): BOOLEAN

Returns true if tag is an XML element with the name name in namespace namespace. Note that namespace is the full URI, not an abbreviation. Also, namespace may be null, in which case tag must not have a namespace associated with it.

xml-attribute-match? (attribute (name STRING)

[Method on XML-ATTRIBUTE]

(namespace String)): Boolean

Return true if attribute is an XML attribute with name name in namespace namespace. Note that namespace is the full URI, not an abbreviation. Also, namespace may be null, in which case attribute must not have a namespace associated with it.

xml-attribute-match? (attribute [Method on XML-GLOBAL-ATTRIBUTE] (name STRING) (namespace STRING)): BOOLEAN

Return true if attribute is a global XML attribute with name name in namespace namespace. Note that namespace is the full URI, not an abbreviation. Also, namespace may be null, in which case attribute must not have a namespace associated with it.

xml-attribute-match? (attribute [Method on XML-LOCAL-ATTRIBUTE] (name STRING) (namespace STRING)): BOOLEAN

Return true if attribute is a local XML attribute with name name. Note that namespace must be null and that the attributes parent element element is not considered by the match. To take the parent element into account use xml-local-attributematch?.

Return true if attribute is a local attribute with name and whose parent element matches element-name and element-namespace.

Find the XML attribute in attributes with name and namespace and return its value. Note that it is assumed that all attributes come from the same known tag, hence, the parent elements of any local attributes are not considered by the lookup.

A case form for matching item against XML element tags. Each element of clauses should be a clause with the form ("tagname" ...) or (("tagname" "namespace-uri") ...) The clause heads can optionally be symbols instead of strings. The key forms the parameters to the method xml-element-match?, with a missing namespace argument passed as NULL.

The namespace argument will be evaluated, so one can use bound variables in place of a fixed string. As a special case, if the namespace argument is :ANY, then the test will be done for a match on the tag name alone.

read-xml-expression ((stream INPUT-STREAM) (start-tag OBJECT)): [Function] OBJECT BOOLEAN

Read one balanced XML expression from *stream* and return its s-expression representation (see xml-token-list-to-s-expression). If startTagName is non-'null', skip all tags until a start tag matching *start-tag* is encountered. XML namespaces are ignored for outside of the start tag. Use s-expression representation to specify *start-tag*, e.g., (KIF (:version "1.0")). The tag can be an XML element object, a symbol, a string or a cons. If the tag is a cons the first element can also be (name namespace) pair.

Return true as the second value on EOF.

CHANGE WARNING: It is anticipated that this function will change to a) Properly take XML namespaces into account and b) require XML element objects instead of strings as the second argument. This change will not be backwards-compatible.

xml-expressions ((stream input-stream) (regionTag object)): [Function] XML-EXPRESSION-ITERATOR

Return an XML-expression-iterator (which see) reading from *stream.* regionTag can be used to define delimited regions from which expressions should be considered. Use s-expression representation to specify regionTag, e.g., (KIF (:version "1.0")). The tag can be an XML element object, a symbol, a string or a cons. If the tag is a cons the first element can also be (name namespace) pair.

print-xml-expression ((stream OUTPUT-STREAM) [Function] (xml-expression CONS) (indent INTEGER)):

Prints *xml-expression* on *stream*. Indentation begins with the value of *indent*. If this is the **null** integer, no indentation is performed. Otherwise it should normally be specified as 0 (zero) for top-level calls.

It is assumed that the *xml-expression* is a well-formed CONS-list representation of an XML form. It expects a form like that form returned by read-XML-expression.

Also handles a list of xml forms such as that returned by XML-expressions. In that case, each of the forms is indented by *indent* spaces.

reset-xml-hash-tables ():

[Function]

[Function]

Resets Hashtables used for interning XML elements and global attribute objects. This will allow garbage collection of no-longer used objects, but will also mean that newly parsed xml elements and global attributes will not be eq? to already existing ones with the same name.

6.19 Miscellaneous

This is a catch-all section for functions and methods that haven't been categorized yet into any of the previous sections. They are in random order and many of them will never be part of the official STELLA interface. So beware!

```
operating-system (): KEYWORD

Not documented.
```

Return the element of self at position [i].

1d-aref-address (self (i INTEGER)) : [Method on DIMENSIONAL-ARRAY-MIXIN] INTEGER

Return the 1D address of the element at position [i]. This is useful for fast element-wise iteration that doesn't need arithmetic.

```
1d-aref-setter (self [Method on DIMENSIONAL-ARRAY-MIXIN] (value (LIKE (ANY-VALUE SELF))) (i INTEGER)) : (LIKE (ANY-VALUE SELF))
Set the element of self at position [i] to value and return the result.
```

```
2d-aref (self (i integer) (j integer)): [Method on 2-dimensional-array-mixin] (Like (any-value self))
Return the element of self at position [i, j].
```

2d-aref-address (self (i INTEGER) [Method on 2-DIMENSIONAL-ARRAY-MIXIN] (j INTEGER)): INTEGER

Return the 1D address of the element at position [i, j]. This is useful for fast element-wise iteration that doesn't need arithmetic.

2d-aref-setter (self [Method on 2-DIMENSIONAL-ARRAY-MIXIN] (value (LIKE (ANY-VALUE SELF))) (i INTEGER) (j INTEGER)) : (LIKE (ANY-VALUE SELF))

Set the element of self at position [i, j] to value and return the result.

abs (x): LONG-INTEGER

[Method on LONG-INTEGER]

Return the absolute value of x.

activate-demon ((demon DEMON)):

[Function]

Install demon in the location(s) specified by its internal structure.

active? (self): BOOLEAN [Method on POLYMORPHIC-RELATION]
True if self or a superslot of self is marked active.

add-configuration-property ((property STRING) (value OBJECT) [Function] (configuration CONFIGURATION-TABLE)): OBJECT

Add value to property in configuration and return it. If a previous value exists add value to the end (listify the old value if it is not yet a list). Otherwise, create a new list containing value. Use the global system configuration table if configuration is NULL.

add-current-date-substitution

[Function]

((substitution-list (key-value-list of string-wrapper string-wrapper))):

Fill in *substitution-list* with date information for the current date and time. See add-date-substitution for details.

```
add-date-substitution ((date CALENDAR-DATE) [Function] (substitution-list (KEY-VALUE-LIST OF STRING-WRAPPER STRING-WRAPPER)))
```

Fill in *substitution-list* with template variable substitions for the names YEAR, MONTH, MON, DAY, HOUR, MINUTE, SECOND, TIMEZONE, DAY-OF-WEEK, DOW with their values for *date*. Also, pre-formatted DATE, TIME and ISO8601 variables are set.

TIMEZONE is in the format "{+|-}hhmm". MONTH is the full English month name and MON is the numeric month. DAY-OF-WEEK is an English string and DOW is the first three letters. Minutes and seconds are zero-padded.

These substitutions can be used with substitute-template-variables-in-string

add-hook ((hookList hook-list) (hookFunction symbol)): [Function]
Insert the function named hookFunction into hookList.

add-load-path ((path STRING)): (CONS OF STRING-WRAPPER) [Command]
Append the directories listed in the |-separated path to the end of the STELLA load path. Return the resulting load path.

add-property-value ((property NAME) (value OBJECT)): [Command]

Add value to the end of propertys (a string or symbol) value list in the configuration table. Coerces the current value to a list or initializes the list if it is as yet undefined. Allows incremental addition of values to list-valued propertys. Note that property is evaluated and will need to be quoted if supplied as a symbol. Symbols will also be upcased if this command is run in a non-case-sensitive module.

- add-trace (&rest (keywords GENERALIZED-SYMBOL)): LIST [N-Command]
 Enable trace messages identified by any of the listed keywords. After calling
 (add-trace <keyword>) code guarded by (trace-if <keyword> ...) will be executed
 when it is encountered.
- advance-past-whitespace ((source STRING) (start INTEGER)): [Function]

Returns the first index into *source*, starting from *start*, of the first character that is not white space.

all-classes ((module MODULE) (local? BOOLEAN)) : (ITERATOR OF [Function] CLASS)

Iterate over all classes visible from *module*. If *local?*, return only classes interned in *module*. If *module* is null, return all classes interned everywhere.

- all-contexts (): (ITERATOR OF CONTEXT) [Function]
 Return an iterator that generates all contexts.
- all-defined? (&body (forms CONS)): OBJECT [Macro] Evaluate each of the forms in forms, and return TRUE if none of them are NULL.
- all-functions ((module MODULE) (local? BOOLEAN)): (ITERATOR OF [Function] FUNCTION)

 Iterate over all functions visible from module. If local?, return only functions bound to

symbols interned in module. If module is null, return all functions defined everywhere.

- all-included-modules ((self module)): (ITERATOR OF MODULE) [Function]
 Generate a sequence of all modules included by self, inclusive, starting from the highest ancestor and working down to self (which is last).
- all-methods ((module MODULE) (local? BOOLEAN)) : (ITERATOR OF [Function] METHOD-SLOT)

Iterate over all methods visible from *module*. If *local?*, return only methods interned in *module*. If *module* is null, return all methods interned everywhere.

all-modules (): (ITERATOR OF MODULE) [Function]
Return an iterator that generates all modules.

all-public-functions ((module MODULE) (local? BOOLEAN)): [Function] (ITERATOR OF FUNCTION)

Iterate over all functions visible from *module*. If *local?*, return only functions bound to symbols interned in *module*. If *module* is null, return all functions defined everywhere.

all-public-methods ((module MODULE) (local? BOOLEAN)): [Function] (ITERATOR OF METHOD-SLOT)

Iterate over all public methods visible from *module*. If *local?*, return only methods interned in *module*. If *module* is null, return all methods interned everywhere.

all-required-systems ((system-name STRING)) : (CONS OF STRING-WRAPPER) [Function]

Returns a CONS of all of the systems required by system-name

all-slots ((module MODULE) (local? BOOLEAN)) : (ITERATOR OF SLOT) [Function]

Iterate over all slots visible from *module*. If *local?*, return only methods interned in *module*. If *module* is null, return all methods interned everywhere.

all-subcontexts ((context CONTEXT) (traversal KEYWORD)): [Function] (ALL-PURPOSE-ITERATOR OF CONTEXT)

Return an iterator that generates all subcontexts of **self** (not including **self**) in the order specified by *traversal* (one of :preorder, :inorder, :postorder or :topdown).

all-surrogates ((module MODULE) (local? BOOLEAN)) : (ITERATOR [Function] OF SURROGATE)

Iterate over all surrogates visible from *module*. If *local?*, return only surrogates interned in *module*. If *module* is null, return all surrogates interned everywhere.

all-symbols ((module MODULE) (local? BOOLEAN)) : (ITERATOR OF SYMBOL)

Iterate over all symbols visible from *module*. If *local?*, return only symbols interned in *module*. If *module* is null, return all symbols interned everywhere.

all-variables ((module MODULE) (local? BOOLEAN)) : (ITERATOR OF GLOBAL-VARIABLE)

Iterate over all variables visible from module. If local?, return only variables bound to symbols interned in module. If module is null, return all variables defined everywhere.

allocate-cross-product-iterator ((domains (CONS OF CONS))): [Function] CROSS-PRODUCT-ITERATOR

Allocate a cross product iterator for a list of domains.

allocate-iterator (self): (LIKE SELF) [Method on ABSTRACT-ITERATOR] Iterator objects return themselves when asked for an iterator (they occupy the same position as a collection within a foreach statement).

allocate-iterator (self): (ITERATOR OF [Method on MEMOIZABLE-ITERATOR] (LIKE (ANY-VALUE SELF)))
Alias for clone-memoized-iterator.

allocation (self): KEYWORD [Method on STORAGE-SLOT]
Return the most specific :allocation facet, or :instance if all inherited values are NULL.

append-character (self (char CHARACTER)): [Method on BUFFERED-STRING] Append char to the END of the string self. Resize the buffer if necessary.

append-string (self (value STRING)): [Method on BUFFERED-STRING]
Append value to the END of the string self. Resize the buffer if necessary.

apply ((code function-code) (arguments (cons of object))): [Function]

Apply code to arguments, returning a value of type OBJECT. Currently limited to at most 10 arguments.

apply-boolean-method ((code METHOD-CODE)

[Function]

(arguments (CONS OF OBJECT))): BOOLEAN

Apply code to arguments, returning a value of type BOOLEAN.

apply-float-method ((code METHOD-CODE)

[Function]

(arguments (CONS OF OBJECT))): FLOAT

Apply code to arguments, returning a value of type FLOAT.

apply-integer-method ((code METHOD-CODE)

[Function]

(arguments (CONS OF OBJECT))): INTEGER

Apply code to arguments, returning a value of type INTEGER.

apply-long-integer-method ((code METHOD-CODE)

[Function]

(arguments (CONS OF OBJECT))): LONG-INTEGER

Apply code to arguments, returning a value of type LONG-INTEGER.

apply-method ((code METHOD-CODE) (arguments (CONS OF OBJECT))): [Function] OBJECT

Apply code to arguments, returning a value of type OBJECT.

apply-string-method ((code METHOD-CODE)

[Function]

(arguments (CONS OF OBJECT))): STRING

Apply code to arguments, returning a value of type STRING.

autoload ((qualifiedName STRING) (systemName STRING)

[Function]

(cache surrogate) (error? BOOLEAN)): FUNCTION-CODE

Autoload function qualifiedName from system systemName. If it is already present in the system, simply return its code. If cache is defined, return its value if defined, otherwise, set its value to the function found. If the function failed to be defined by loading systemName and error? is true, raise an error. Otherwise, simply return NULL.

base60-to-float ((l (CONS OF NUMBER-WRAPPER))): FLOAT [Function] Converts (x y z) into a float. The return value is x + y/60 + z/3600. This can be used to convert from Degree-Minute-Second to decimal degrees or from Hour-Minute-Second format to decimal hours.

blank-string? ((string STRING)) : BOOLEAN

[Function]

Return true if string is either NULL, empty, or only contains white space characters.

break-program ((message STRING)):

[Command]

Interrupt the program and print message. Continue after confirmation with the user.

bump-log-indent () :

[Command]

Increase the indentation level for subsequent log messages.

byte-array-read-sequence ((buffer TOKENIZER-BYTE-ARRAY)

[Function]

(stream input-stream) (start integer) (end integer)): integer Read from stream filling buffer between start and end (depending on how many

characters are available). Return the actual end pointer to the input read into buffer. EOF is indicated by the return value being equal to start.

byte-array-write-sequence ((buffer TOKENIZER-BYTE-ARRAY) [For the sequence (stream Native-Output-Stream) (start integer) (end integer)):

[Function]

Write from buffer to stream, using data in the buffer starting at position start stopping just before end.

calendar-date-to-date-string (date

[Method on CALENDAR-DATE]

(timezone float) (numeric-month? BOOLEAN)): STRING

Returns the date part of the string representation of *date* adjusted for *timezone*. Format is YYYY-MMM-DD, where MMM is a three letter English abbreviation of the month if *numeric-month?* is false and a two digit numeric value if *numeric-month?* is true. The value false is recommended.

calendar-date-to-iso8601-string (date

[Method on CALENDAR-DATE]

(timezone float) (include-timezone? Boolean)) : String

Returns an ISO-8601 string representation of *date* adjusted for *timezone*. The Format is YYYY-MM-DDThh:mm:ss z:zz. The timezone as an offset hh:mm is included if *include-timezone*? is true.

Recommended values for the flag is true.

calendar-date-to-string (date (timezone FLOAT) [Method on CALENDAR-DATE] (numeric-month? BOOLEAN) (include-timezone? BOOLEAN)): STRING

Returns a string representation of *date* adjusted for *timezone*. The Format is YYYY-MMM-DD hh:mm:ss z.z, where MMM is a three letter English abbreviation of the month if *numeric-month*? is false and a two digit numeric value if *numeric-month*? is true. The timezone as a float offset z.z is included if *include-timezone*? is true.

Recommended values for the flags are false and true respectively.

calendar-date-to-time-string (date

[Method on Calendar-Date]

(timezone float) (include-timezone? Boolean)

(include-millis? BOOLEAN) (pad-hours? BOOLEAN)): STRING

Returns the time part of the string representation of date adjusted for timezone. The timezone is included in the string if include-timezone? is true. The value true is recommended. Milliseconds will be included if include-millis? is true. Hours will be zero-padded to length 2 if pad-hours? is true.

call-clear-module (&rest (name NAME)):

[Command]

Destroy all objects belonging to module *name* or any of its children. If no *name* is supplied, the current module will be cleared after confirming with the user. Important modules such as STELLA are protected against accidental clearing.

canonical-slot ((slot STORAGE-SLOT)) : STORAGE-SLOT

[Function]

Computes the slot at the base of a renaming chain for slot.

canonical-slot-name ((slot STORAGE-SLOT)) : SYMBOL

[Function]

Name of the slot at the base of a renaming chain for slot.

cast ((value object) (type type)): object

[Function]

Perform a run-time type check, and then return value.

ccc (&rest (name NAME)) : CONTEXT

[N-Command]

Change the current context to the one named name. Return the value of the new current context. If no name is supplied, return the pre-existing value of the current context. cc is a no-op if the context reference cannot be successfully evaluated. In CommonLisp, if the new context is case sensitive, then change the readtable case to the value of CL-USER::*STELLA-CASE-SENSITIVE-READ-MODE* [default = :INVERT], otherwise to :UPCASE.

cl-slot-value ((object object) (slotName STRING)

[Function]

(dontConvert? BOOLEAN)): LISP-CODE

Lookup slot slotName on object and return the lispified slot value (see lispify). If dontConvert? is TRUE, the returned slot value will not be lispified. Generate a warning if no such slot exists on *object*. In a call directly from Lisp slotName can also be supplied as a Lisp symbol.

cl-slot-value-setter ((object object) (slotName STRING)

[Function]

(value LISP-CODE) (dontConvert? BOOLEAN)): LISP-CODE

Lookup slot slotName on object and set its value to the stellafied value (see stellafy). If dontConvert? is TRUE, value will not be stellafied before it gets assigned. Generate a warning if no such slot exists on object, or if value has the wrong type. In a call directly from Lisp slotName can also be supplied as a Lisp symbol.

cl-translate-file ((file FILE-NAME) (relative? BOOLEAN)): Translate a Stella file to Common-Lisp. If relative?, concatenate root directory to

[Function]

file.

cl-translate-system ((system-name STRING)) :

[Function]

Translate a Stella system named system-name to Common Lisp.

cleanup-unfinalized-classes ():

[Function]

Remove all finalized classes from *UNFINALIZED-CLASSES*. and set *NEWLY-UNFINALIZED-CLASSES?* to false.

clear (self):

[Method on Vector-sequence]

Clear self by setting its active length to zero.

clear (self):

[Method on HEAP]

Clear self by setting its active length to zero.

clear (self):

[Method on Buffered-String]

Clear self by setting its active length to zero.

clear-configuration-property ((property STRING)

[Function]

(configuration configuration-table)): Object

Remove property in configuration and return the previous value. Use the global system configuration table if configuration is NULL.

clear-input ((self INPUT-STREAM)) :

[Function]

Clear all buffered raw and tokenized input of self.

clear-recycle-list ((list RECYCLE-LIST)) :

[Function]

Reset *list* to its empty state.

clear-recycle-lists () :

[Function]

Reset all currently active recycle lists to their empty state.

clear-system ((name STRING)) :

[Function]

Clears out the system definition named name. If name is null, then clear out all system definitions. This function is useful when changes have been made to the system definition, and one wants to have it reloaded from the standard location in the file system.

clear-trace () :

[Command]

Disable all tracing previously enabled with add-trace.

clone-memoized-iterator ((self MEMOIZABLE-ITERATOR)) :

[Function]

(ITERATOR OF (LIKE (ANY-VALUE SELF)))

Clone the memoized iterator *self* so it can be used to iterate over the collection represented by *self*, while allowing to iterate over it multiple times via multiple clones.

clv ((code OBJECT)) : OBJECT

[Macro]

Convenience macro to splice Lisp expressions into STELLA expressions without upsetting the translator during interactive sessions. If *code* is a currently bound Lisp variable, this tries to infer the type of the resulting expression from the object *code* is bound to and generates an appropriate cast. clv stands for Common-Lisp Value or Verbatim.

coerce-&rest-to-cons ((restVariable SYMBOL)): OBJECT

[Macro]

Coerce the argument list variable restVariable into a CONS list containing all its elements (uses argument list iteration to do so). If restVariable already is a CONS due to argument listification, this is a no-op.

$\verb|coerce-option-value| ((value | \verb|object|) | (type | \verb|type|)) : \verb|object||$

[Function]

Coerce value to type. Return NULL if not possible.

coerce-to-boolean ((object OBJECT)) : BOOLEAN-WRAPPER

[Function]

Return the boolean object represented by *object*. Return NULL if coercion is not possible.

coerce-to-float ((object OBJECT)) : FLOAT

[Function]

Coerce number to a float value or NULL if not possible.

```
coerce-to-hash-set ((self OBJECT) (equalTest? BOOLEAN)): [Function]
HASH-SET
```

Coerce the collection self into a HASH-SET. Use an equal test if equalTest? is TRUE (equalTest? will be ignored if self already is a HASH-SET).

```
coerce-to-string ((object object)) : STRING
```

[Function]

Coerce object into a string. If no standard coercion is possible, simply stringify object.

```
coerce-to-symbol ((name NAME)) : GENERALIZED-SYMBOL
```

[Function]

Return the (generalized) symbol represented by *name*. Return **null** if *name* is undefined or does not represent a string.

```
coerce-value-to-boolean ((value OBJECT) (error? BOOLEAN)): [Function]
```

Return the boolean object represented by *value*. Return NULL if coercion is not possible or raise an error if *error*? is TRUE.

coerce-value-to-float ((value OBJECT) (error? BOOLEAN)): FLOAT [Function] Coerce value to a float value if possible, return NULL otherwise or raise an error if error? is true.

```
coerce-value-to-string ((value OBJECT) (error? BOOLEAN)) : [Function]
```

Coerce value into a string if possible, return NULL otherwise or raise an error if error? is true.

```
coerce-value-to-type ((value OBJECT) (type TYPE) [Function] (error? BOOLEAN)): OBJECT
```

Coerce value to type. Return NULL if not possible or raise an error if error? is TRUE.

```
collect (&body (body cons)) : OBJECT
```

[Macro]

Use a VRLET to collect values. Input can have one of the following forms:

The second form really accepts an arbitrary foreach expression following the foreach keyword.

```
collection-valued? (self) : BOOLEAN
```

[Method on Slot]

True if slot values are collections.

```
\verb|command?| ((method \verb|METHOD-SLOT|)) : \verb|BOOLEAN||
```

[Function]

Return true if method is an evaluable command.

```
compare-strings ((x STRING) (y STRING) (collation KEYWORD)): [Function]
INTEGER
```

Compare x and y and return -1, 0, or 1, depending on whether x is less than, equal, or greater than y relative to collation. Currently supported values for collation are

:ascii-case-sensitive, :ascii-case-insensitive :ascii-case-normalized. The first two correspond to string-compare called with the appropriate third argument. :ascii-case-normalized calls the function string-compare-case-normalized (which see).

component? (self): BOOLEAN

[Method on STORAGE-SLOT]

True if fillers of this slot are components of the owner slot, and therefore should be deleted if the owner is deleted.

compose-namestring

[Function]

((name-components (CONS OF STRING-WRAPPER)) & rest (options OBJECT))

name-components is a cons to be processed into a namestring. :prefix and :suffix are strings that will NOT be case-converted. :case is one of :UPCASE :TitleCase :titleCaseX :downcase :Capitalize default is :TitleCase :separator is a string that should separate word elements. It does not separate the prefix or suffix. Default is "" :translation-table should be a STRING-HASH-TABLE hash table that strings into their desired printed representation as a string. In general the argument will be strings, but that is not strictly necessary.

```
compose-namestring-full ((strings (cons of string-wrapper)) [Function] (prefix string) (suffix string) (outputcase keyword) (outputseparator string) (translationtable string-hash-table) (useacronymheuristics? BOOLEAN)): string
```

Non-keyword version of compose-namestring, which will probably be easier to use when called from non-Lisp languages.

- compute-module-and-bare-name ((name STRING)): MODULE STRING [Function] Compute the module indicated by the STELLA name name and return it. Return the bare symbol name as the second value. name does not necessarily have to be qualified in which case the current module is returned. name is assumed to be the printed representation of a STELLA symbol, surrogate or keyword.
- compute-system-root-directories ((system System-Definition)): [Function] Compute any root directories for sources, native and Lisp binary directories in case they were not explicitly specified in systems definition. Raises an error in case any of those root directories is missing and can't be computed.

```
concatenate-file-names ((file FILE-NAME)
```

[Function]

&rest (otherFiles file-name)): file-name

Intelligently join file and other Files into a concatenated path where each component is separated by a single separator (similar to Python's os.path.join). Keeps the result a logical pathname as long as possible, but converts to physical as soon as any of other Files contain a physical directory separator.

Load the configuration file *value*. This will modify currently set system properties defined in *value* with new values but leave all other currently set properties as they are.

other non-standard types.

configure-stella ((file FILE-NAME)): [Command] Perform STELLA run-time configuration. If supplied, load the configuration file file first which should be supplied with a physical pathname. consify (self): CONS [Method on OBJECT] If object is a CONS, return it. Otherwise, return a singleton cons list containing it. consify-command-line-arguments ((count integer) [Function] (arguments (ARRAY () OF STRING))): (CONS OF STRING-WRAPPER) Convert count command line arguments into a CONS list. continuable-error (&body (body CONS)) : OBJECT [Macro] Signal error message, placing non-string arguments in quotes. copy (self): (VECTOR-SEQUENCE OF (LIKE [Method on Vector-sequence] (ANY-VALUE SELF))) Return a copy of the vector sequence self. copy (self): (CUSTOM-VECTOR-SEQUENCE [Method on Custom-Vector-sequence] OF (LIKE (ANY-VALUE SELF))) Return a copy of the vector sequence self. copy (self): (HEAP OF (LIKE (ANY-VALUE SELF))) [Method on HEAP] Return a copy of the heap self. copy (string): MUTABLE-STRING [Method on MUTABLE-STRING] Return a copy of string. copy-stream-to-stream ((in INPUT-STREAM) (out OUTPUT-STREAM)): [Function] Copy in verbatimely to out. Does the right thing for binary data. cpp-find-native-slot-value-offset ((self STANDARD-OBJECT) [Function] (slot storage-slot)) : integerDynamically determine the byte offset where the native value for slot starts in self. This basically performs the function of the C++ macro offsetof but does it dynamically. Of course, it relies on a working read/write-slot-value mechanism and we currently primarily use this for the Python API. This basically writes value changes of slot to determine a byte position where a change occurred and then restores the original value (which can be NULL). This handles all native OBJECT and LITERAL slots but does not handle special slots such as dynamic-slots or hardwired slots or

cpp-translate-system ((systemName STRING)):

Translate the system systemName to C++.

cpptrans ((statement OBJECT)):

Translate statement to C++ and print the result.

[N-Command]

create-derived-list ((self LIST)): LIST [Function]

Create a new list object with the same type as self.

create-directories ((directory STRING)) :

[Command]

If directory does not yet exist, create it and any of its parents that do not yet exist. If directory already does exist, this simply is a no-op.

create-object ((type TYPE) & rest (initial-value-pairs OBJECT)): [Function]

Funcallable version of the new operator. Return an instance of the class named by type. If initial-value-pairs is supplied, it has to be a key/value list similar to what's accepted by new and the named slots will be initialized with the supplied values. Similar to new, all required arguments for type must be included. Since all the slot initialization, etc. is handled dynamically at run time, create-object is much slower than new; therefore, it should only be used if type cannot be known at translation time.

date-to-version-string ((date CALENDAR-DATE)

[Function]

(granularity Keyword)): String

Transform date into a version string according to granularity which is at least :days and defaults to :seconds.

deactivate-demon ((demon DEMON)):

[Function]

Detach demon from the location(s) specified by its internal structure.

decoded-date-time-to-iso8601-string

[Method on DECODED-DATE-TIME]

(date): STRING

Returns an ISO-8601 string representation of date The Format is YYYY-MM-DDThh:mm:ss+zz:zz, with the string stopping at when a null value is first encountered. The time zone will only be included (if present) if a time value is given.

decompose-namestring ((namestring STRING)

[Function]

&rest (options object)): (cons of string-wrapper)

Keyword options: :break-on-cap one of :YES :NO :CLEVER default is :CLEVER :break-on-number one of :YES :NO :CLEVER default is :CLEVER :break-on-separators string default is "-_ "

DECOMPOSE-NAMESTRING returns a cons of STRING-WRAPPERS that are the decomposition of the input STRING. The arguments are used as follows: namestring is the input string. :break-on-cap is a keyword controlling whether changes in capitalization is used to indicate word boundaries. If :YES, then all capitalization changes delineate words. If :CLEVER, then unbroken runs of capitalized letters are treated as acronyms and remain grouped. If :NO or NULL, there is no breaking of words based on capitalization. :break-on-number is a flag controlling whether encountering a number indicates a word boundary. If :YES, then each run of numbers is treated as a word separate from surrounding words. If :CLEVER, then an attempt is made to recognize ordinal numbers (ie, 101st) and treat them as separate words. If :NO or NULL, there is no breaking of words when numbers are encountered. :break-on-separators A string of characters which constitute word delimiters in the input word. This is used to determine how to break the name into individual words. Defaults are space, – and _.

decompose-namestring-full ((namestring STRING)

[Function]

(break-on-cap KEYWORD) (break-on-number KEYWORD)

(break-on-separators string)): (cons of string-wrapper)

Non-keyword version of decompose-namestring, which will probably be easier to use when called from non-Lisp languages.

[Function]

Default handler that tries to set a system property based on option and value.

default-form (self) : OBJECT

[Method on STORAGE-SLOT]

Returns the current value of default expression when the slot has not been assigned a value.

defdemon ((name STRING-WRAPPER) (parameterstree CONS)

[Macro]

&body (options and body cons)): OBJECT

Define a demon name and attach it to a class or slot.

define-demon ((name STRING) & rest (options OBJECT)): DEMON [Function] Define a class or slot demon. Options are :create, :destroy, :class, :slot, :guard?, :code,

:method, :inherit?, and :documentation.

${\tt define-global-variable-object} \ ((definition \ {\tt STRING})$

[Function]

(nativeObject native-object-pointer)):

Define a STELLA global variable object based on *definition*, and initialize its variable-native-object slot to *nativeObject* (which is primarily needed for C++).

${\tt define-logical-host-property}\ ((host\ {\tt STRING})$

[Command]

(property KEYWORD) (value OBJECT)):

Define property with value for the logical host host. As a side-effect, this also defines host as a logical host (both property and value can be supplied as NULL). If :ROOT-DIRECTORY is specified, all pathnames with host are assumed to be relative to that directory (even if they are absolute) and will be rerooted upon translation. :ROOT-DIRECTORY can be a logical or physical pathname. If :LISP-TRANSLATIONS is specified, those will be used verbatimely as the value of (CL:logical-pathname-translations host) if we are running in Lisp, which allows us to depend on the native CL:translate-logical-pathname for more complex translation operations.

define-module ((name STRING) (options CONS)): MODULE

[Function]

Define or redefine a module named name having the options options. Return the new module.

define-stella-class ((name TYPE) (supers (LIST OF TYPE))

[Function]

(slots (List of Slot)) (options keyword-key-value-list)) : class

Return a Stella class with name name. Caution: If the class already exists, the Stella class object gets redefined, but the native C++ class is not redefined.

define-stella-global-variable-from-stringified-source

[Function]

((stringifiedSource STRING)):

Define a stella global variable using a parse tree derived from stringifiedSource.

define-stella-method-slot ((inputname SYMBOL)

[Function]

(returntypes cons) (function? BOOLEAN) (inputParameters cons)

(options keyword-key-value-list)) : method-slot

Define a new Stella method object (a slot), and attach it to the class identified by the first parameter in *inputParameters*.

defined? (x): BOOLEAN

[Method on LONG-INTEGER]

Return true if x is defined (handled specially by all translators).

defined? (x): BOOLEAN

[Method on ARRAY]

Return true if x is defined (handled specially by all translators).

defmain ((varList cons) &body (body cons)) : OBJECT

[Macro]

Defines a function called MAIN which will have the appropriate signature for the target translation language. The signature will be: C++: public static int main (int v1, char** v2) {<body>} Java: public static void main (String [] v2) {<body>} Lisp: (defun main (&rest args) <body>) The argument varList must have two symbols, which will be the names for the INTEGER argument count and an array of STRINGs with the argument values. It can also be empty to indicate that no command line arguments will be handled. The startup function for the containing system will automatically be called before body is executed unless the option :STARTUP-SYSTEM? was supplied as FALSE. There can only be one DEFMAIN per module.

defsystem ((name SYMBOL) & rest (options OBJECT)): SYSTEM-DEFINITION

[N-Command]

Define a system of files that collectively define a Stella application. Required options are: :directory – the relative path from the respective source/native/binary root directory to the directory containing the system files. Can be a string or a list of strings (do not include directory separators). :files – a list of files in the system, containing strings and lists of strings; the latter defines exploded paths to files in subdirectories. Optional options are: :data-files – a list of files like the :files keyword, which contain data or other content that should not be processed, but instead copied verbatim to the native directory :required-systems – a list of systems (strings) that should be loaded prior to loading this system. :cardinal-module – the name (a string) of the principal module for this system. :copyright-header – string with a header for inclusion into all translated files produced by Stella. :lisp-only-files – Like the :files keyword, but these are only included :cpp-only-files in the translation for the specific language, namely :java-only-files Common Lisp, C++ or Java

deleted? (self): BOOLEAN

[Method on OBJECT]

Default deleted? method which always returns FALSE. Objects that inherit DYNAMIC-SLOTS-MIXIN also inherit the dynamically-allocated slot deleted-object? which is read/writable with specializations of this method.

describe ((name object) &rest (mode object)):

[N-Command]

Print a description of an object in :verbose, :terse, or :source modes.

describe-object (self (stream OUTPUT-STREAM) [Method on OBJECT] (mode KEYWORD)):

Prints a description of self to stream stream. mode can be :terse, :verbose, or :source. The :terse mode is often equivalent to the standard print function.

destroy-class (self):

[Method on CLASS]

Destroy the Stella class self. Unfinalize its subclasses (if it has any).

destroy-class-and-subclasses ((self CLASS)):

[Function]

Destroy the Stella class self and all its subclasses.

destructure-defmethod-tree ((method-tree CONS)

[Function]

(options-table key-value-list)) : object cons cons

Return three parse trees representing the name, parameters, and code body of the parse tree method-tree. Fill options-table with a dictionary of method options. Storage note: Options are treated specially because the other return values are subtrees of method-tree, while options-table is a newly-created cons tree. Note also, the parameter and body trees are destructively removed from method-tree.

dictionary ((collectionType TYPE)

[Function]

&rest (alternatingkeysandvalues object)): (Abstract-dictionary of object object)

Return a dictionary of *collectionType* containing values, in order. Currently supported *collectionTypes* are @HASH-TABLE, @STELLA-HASH-TABLE, @KEY-VALUE-LIST, @KEY-VALUE-MAP and @PROPERTY-LIST.

direct-super-classes (self): (ITERATOR OF CLASS)

[Method on CLASS]

Returns an iterator that generates all direct super classes of self.

disable-memoization ():

[Command]

Enable memoization and use of memoized expression results.

disabled-stella-feature? ((feature KEYWORD)): BOOLEAN Return true if the STELLA feature is currently disabled.

[Function]

disjoint-sets? (self (otherList cons)) : BOOLEAN

[Method on CONS]

Return true if the intersection of self and otherList is empty. This is always true if at least one of the two sets is the empty set. Uses an eql? test and a simple quadratic-time algorithm. Note that this does not check whether self and otherList actually are sets.

 $\operatorname{div}\left(x\left(y\right)\right)$: INTEGER

[Method on Integer]

Return the integer quotient from dividing x by y.

div (x (y LONG-INTEGER)): LONG-INTEGER Return the integer quotient from dividing x by y. [Method on LONG-INTEGER]

drop-hook ((hookList HOOK-LIST) (hookFunction SYMBOL)):

[Function]

Remove the function named hookFunction from hookList.

drop-load-path ((path STRING)): (CONS OF STRING-WRAPPER) [Command]
Remove the directories listed in the |-separated path from the PowerLoom load path.

drop-slot-value ((self STANDARD-OBJECT) (slot STORAGE-SLOT) [Function] (value OBJECT)):

Clear or remove value for the slot slot on self. CAUTION: Assumes that collection-valued slots are non-null.

- drop-trace (&rest (keywords GENERALIZED-SYMBOL)): LIST [N-Command]

 Disable trace messages identified by any of the listed keywords. After calling (drop-trace <keyword>) code guarded by (trace-if <keyword> ...) will not be executed when it is encountered.
- eight-bit-character? ((ch Character)): BOOLEAN [Function]
 Return TRUE if ch is in the upper half of the byte set such as UTF-8 codes, etc.
- either ((value1 object) (value2 object)): object [Macro] If value1 is defined, return that, else return value2.
- empty? (x): BOOLEAN [Method on STRING-WRAPPER]
 Return true if x is the wrapped empty string ""
- empty? (self): BOOLEAN [Method on VECTOR-SEQUENCE]
 Return true if self has length 0.
- empty? (self): BOOLEAN [Method on HEAP]
 Return TRUE if self is empty.
- empty? (self): BOOLEAN [Method on BUFFERED-STRING]
 Return true if self has length 0.
- enable-memoization (): [Command]

 Enable memoization and use of memoized expression results.
- enabled-stella-feature? ((feature KEYWORD)): BOOLEAN [Function]
 Return true if the STELLA feature is currently enabled.

 ends-with? ((string STRING) (suffix STRING) (end INTEGER)): [Function]

BOOLEAN
Return TRUE if the substring of *string* ending at *end* ends with *suffix*. If *end* is NULL it defaults to the length of *string*.

- ensure-directories-exist ((fileName FILE-NAME)): [Command] Ensure all physical directories in the directory portion of fileName exist.
- ensure-file-does-not-exist ((filename STRING) (context STRING)): [Function] Ensures that filename does not exist. If it does, an exception of type FILE-ALREADY-EXISTS-EXCEPTION is thrown with context supplying context for the error message.
- ensure-file-exists ((filename STRING) (context STRING)): [Function] Ensures that filename exists. If not, an exception of type NO-SUCH-FILE-EXCEPTION is thrown with context supplying context for the error message.
- ensure-free-space (self (size integer)): [Method on Buffered-String]

 MUTABLE-STRING

Ensure self is big enough to accommodate an additional item of size.

eql-except-in-whitespace? ((s1 STRING) (s2 STRING)): BOOLEAN [Function] Return true if the strings s1 and s2 are the same except for the amounts of whitespace separating words. Leading or trailing whitespace is also not considered.

error (&body (body cons)) : OBJECT

[Macro]

Signal error message, placing non-string arguments in quotes.

eval-in-module-option-handler ((option CMD-LINE-OPTION) [Function] (value OBJECT)):

Interpret an —eval-in-module option. *value* is expected to be of the form (<module-name> <s-expression>).

eval-option-handler ((option CMD-LINE-OPTION) (value OBJECT)): [Function] Interpret an -eval option by evaluating value.

evaluate ((expression object)) : object

[Command]

Evaluate the expression expression and return the result. Currently, only the evaluation of (possibly nested) commands and global variables is supported. The second return value indicates the actual type of the result (which might have been wrapped), and the third return value indicates whether an error occurred during the evaluation. Expressions are simple to program in Common Lisp, since they are built into the language, and relatively awkward in Java and C++. Users of either of those languages are more likely to want to call evaluate-string.

evaluate-string ((expression STRING)) : OBJECT

[Function]

Evaluate the expression represented by expression and return the result. This is equivalent to (evaluate (unstringify expression)).

even? (x): BOOLEAN

[Method on INTEGER]

Return true if x is an even number.

even? (x): BOOLEAN

[Method on LONG-INTEGER]

Return true if x is an even number.

exception-context ((e NATIVE-EXCEPTION)) : STRING

[Function]

Print the exception context of e to a string and return the result.

exception-message ((e NATIVE-EXCEPTION)) : STRING

[Function]

Accesses the error message of the exception e.

extension (self): CLASS-EXTENSION

[Method on CLASS]

Return the nearest class extension that records instances of the class self.

external-id-head? ((attribute object)) : BOOLEAN

[Function]

Checks to see if this attribute is the literal marking either a PUBLIC or SYSTEM literal for an XML Elternal ID. (See 4.2.2)

fast-heap-root (self): (LIKE (ANY-VALUE SELF))

[Method on HEAP]

Return the root of *self* which is assumed to be non-empty.

file-name-without-device ((file FILE-NAME)) : FILE-NAME

[Function]

Return the file name portion of *file* by removing any physical device components. This is just like logical-pathname-without-host but only looks for one-character device strings as used in Windows.

file-to-string ((file STRING)) : STRING

[Function]

Read the content of file and return it as a string.

fill-in-date-substitution

[Function]

```
((substitution-list (key-value-list of string-wrapper string-wrapper))) :
```

Fill in *substitution-list* with template variable substitions for the names YEAR and DATE which correspond to the current year and date. These substitutions can then be used with substitute-template-variables-in-string DEPRECATED. Use add-date-substitution or add-current-date-substitution instead.

finalize-classes ():

[Function]

Finalize all currently unfinalized classes.

finalize-classes-and-slots ():

[Function]

Finalize all currently unfinalized classes and slots.

finalize-slots ():

[Function]

Finalize all currently unfinalized slots.

find-file-in-load-path ((file STRING)

[Command]

(extensions (CONS OF STRING-WRAPPER))): STRING

Try to find file in the current load path and, if found, return its full name. If file can't be found literally, try to find it with any of the listed extensions added. If extensions is NULL it defaults to *stella-file-extensions*, therefore, to not default to any extensions the value has to be supplied as NIL.

```
find-matching-prefix-length ((string1 \text{ string}) (start1 \text{ integer}) [Function] (end1 \text{ integer}) (string2 \text{ string}) (start2 \text{ integer}) (end2 \text{ integer}): INTEGER
```

Finds the length of the matching prefix strings of *string1* and *string2*, starting at position *start1* and *start2* respectively. The search will end when *end1* or *end2* is reached. If either *end1* or *end2* is null, then they will be set to the length of their respective strings.

```
find-mismatch ((string1 \text{ string}) (start1 \text{ integer}) (end1 \text{ integer}) [Function] (string2 \text{ string}) (start2 \text{ integer}) (end2 \text{ integer})): integer integer
```

Finds the first position in each of *string1* and *string2* where they mismatch, starting at position *start1* and *start2* respectively. The search will end when *end1* or *end2* is reached. If either *end1* or *end2* is null, then they will be set to the length of their respective strings. If there is no mismatch, then *null* values are returned.

Try to find a STELLA source file based on the name and system components of nativeFileName. This will generally search the current STELLA systems path, since

the tree where a native file resides is not necessarily the one where the corresponding source file is also. This will only work for Lisp and C++ files where the basename of translated files corresponds to the source file from which they were derived. The main purpose for this is to support the Emacs Lisp/STELLA interface to find function definitions.

find-system-definition-file ((name STRING)): FILE-NAME [Function]
Try to find an existing system definition file for a system named name in the current STELLA_SYSTEMS_PATH or built-in implicit systems path. Return NULL if no such definition file can be found. See build-stella-systems-path on where it looks.

find-system-root-directory ((system SYSTEM-DEFINITION)) : [Function]

Given a system definition system try to determine the root directory of the STELLA installation containing this system based on its definition file.

find-system-root-directory-from-file ((sysDefFile FILE-NAME)): [Function] FILE-NAME

Given a system definition file sysDefFile try to determine the root directory of the STELLA installation containing this system by looking for top-level native directories.

first-defined (&body (forms CONS)): OBJECT [Macro]
Return the result of the first form in forms whose value is defined or NULL otherwise.

float-to-base60 ((x FLOAT) (all-integers? BOOLEAN)) : (CONS OF NUMBER-WRAPPER)

Returns a cons of x in a base-60 form. That means the first value will be the integer part of x, the next value the iteger value of the fraction part of x times 60 and the third value the fraction part of x time 3600. If *all-integers?* is **true**, then the last value will be rounded to an integer. This can be used to convert from decimal degree values to Degree-Minute-Second or from decimal hours to Hour-Minute-Second format.

fmod ((x FLOAT) (modulus FLOAT)): FLOAT [Function]

True modulus for floats. Return the result of x mod modulo. Note: In C++ and Java,
mod has more overhead than the similar function rem. The answers returned by mod
and rem are only different when the signs of x and modulo are different.

format-date ((date object) (timezone object) (control string)): [Function]

Format date just like format-date-to-stream (which see), but return the result as a string.

format-date-to-stream ((date OBJECT) (timezone OBJECT) [Function] (control STRING) (stream OUTPUT-STREAM)):

Perform formatted printing of date relative to timezone onto stream. date has to be either a calendar-date or a decoded-date-time object. timezone can be null to indicate the local timezone, or a float or supported timezone name. control is a format control string whose characters are printed literally, unless they are a %-code such as one of these (inspired by the codes supported by the Unix date command): %% a literal

% %a abbreviated weekday name (e.g., Sun) %A full weekday name (e.g., Sunday) %b abbreviated month name (e.g., Jan) %B full month name (e.g., January) %d day of month (e.g., 01) %D date; same as %m/%d/%y %F full date; same as %Y-%m-%d %H hour (00..23) %I hour (01..12) %m month (01..12) %M minute (00..59) %p either AM or PM %r 12-hour clock time (e.g., 11:11:04 PM) %R 24-hour hour and minute; same as %H:%M %S second (00..60) %T time; same as %H:%M:%S %y last two digits of year (00..99) %Y year %z +hhmm numeric time zone (e.g., -04:00) %z alphabetic time zone abbreviation (e.g., EDT) By default, numeric fields are padded with zeroes. The following optional flags may follow %: - (hyphen) do not pad the field _ (underscore) pad with spaces 0 (zero) pad with zeros ^ use upper case if possible , use lower case if possible

format-with-padding ((input STRING) (length INTEGER)

[Function]

(padchar Character) (align Keyword) (truncate? Boolean)): String Formats input to be (at least) length long, using padchar to fill if necessary. align must be one of: LEFT,: RIGHT,: CENTER and will control how input will be justified in the resulting string. If truncate? is true, then then an overlength string will be truncated, using the opposite of align to pick the truncation direction.

free (self): [Method on OBJECT]

Default method. Deallocate storage for self.

Call free on each value in the hash table self.

free (self): [Method on ACTIVE-OBJECT]

Remove all pointers between *self* and other objects, and then deallocate the storage for self.

free-hash-table-values (self): [Method on ABSTRACT-HASH-TABLE]

free-space (self): INTEGER

[Method on BUFFERED-STRING]

Return the amount of free space in self.

frem ((x FLOAT) (y FLOAT)): FLOAT

[Function]

Return the floating point remainder from dividing x by y. The sign of the result is always the same as the sign of x. This has slightly different behavior than the mod function, and has less overhead in C++ and Java, which don't have direct support for a true modulus function.

gc-protect-object ((object NATIVE-OBJECT-POINTER)):

[Function]

NATIVE-OBJECT-POINTER

Protect *object* from garbage collection. Returns a handle that can later be passed to gc-release-object to release *object* from garbage collection protection.

gc-release-object ((handle NATIVE-OBJECT-POINTER)): [Function]

NATIVE-OBJECT-POINTER

Release the object pointed to by *handle* from garbage collection protection and return the protected object. This frees *handle* but does not necessarily mean that the object will be garbage collected, it just can be again, once all references to it disappear.

generate-random-uuid (): STRING

[Function]

Generates a random UUID (Type 4), according to the guidelines of IETF RFC 4122 (see http://www.ietf.org/rfc/rfc4122.txt)

Take 16 random bytes (octets), put them all behind each other, for the description the numbering starts with byte 1 (most significant, first) to byte 16 (least significant, last). Then put in the version and variant. To put in the version, take the 7th byte and perform an and operation using 0x0f, followed by an or operation with 0x40. To put in the variant, take the 9th byte and perform an and operation using 0x3f, followed by an or operation with 0x80. To make the string representation, take the hexadecimal presentation of bytes 1-4 (without 0x in front of it) let them follow by a -, then take bytes 5 and 6, - bytes 7 and 8, - bytes 9 and 10, - then followed by bytes 11-16.

generate-uuid ((uuid-type KEYWORD)) : STRING

[Function]

Generates a UUID of the specified type. Legal types are a subset of the IETF RFC 4122 (see http://www.ietf.org/rfc/rfc4122.txt) UUID types. Currently supported are: :TYPE-4 :RANDOM A type-4 (random) UUID. These are synonyms.

get-calendar-date (date (timezone FLOAT)): [Meth

[Method on CALENDAR-DATE]

Returns multiple values of year, month, day and day of week for date in timezone. timezone is the number of hours added to UTC to get local time. It is in the range -12.0 to +14.0 where UTC is zone 0.0

get-generic-slot-accessor ((slot STORAGE-SLOT) (class CLASS) [Function] (warn? BOOLEAN)): FUNCTION-CODE

Return the accessor code to read *slot* on an object of type *class*, or NULL if no such accessor exists. In that case, print a warning if *warn?* is TRUE. NOTE: the accessor expects canonical-slot-names (which see).

get-global-variable-native-object ((variable GLOBAL-VARIABLE)) [Function] : NATIVE-OBJECT-POINTER

Return the native object of *variable* which can be used to access its runtime value. In Lisp this is the Lisp symbol which holds the variable value, in C++ this is the address of the variable, and in Java this is the declared Field object. For C++ native object addresses are initialized at startup time, for Lisp and Java native objects will be accessed upon first call and then cached in the slot.

${\tt get-language-subdirectory-from-file-type} \ ((type\ {\tt KEYWORD})): \qquad [{\tt Function}]$

Compute a language-specific native subdirectory that should be used for files of type. If type does not naturally suggest which native language it is associated with, key in on the current translation output language. Returns the empty string for unhandled types.

get-load-path (): (CONS OF STRING-WRAPPER) Return the current STELLA load path.

[Command]

get-local-standard-time-zone () : FLOAT

[Function]

Returns the standard time zone offset from UTC as a float, without considering the effects of daylight savings time.

get-local-time-zone-for-date ((year INTEGER) (month INTEGER) [Function] (day integer) (hour integer) (minute integer) (second integer)): FLOAT

Returns the time zone offset from UTC (as a float) that is applicable to the given date. Assumes that the date is one that is valid for the underlying programming language. If not, then returns 0.0

get-log-stream ((module STRING)) : OUTPUT-STREAM

[Function]

Return a valid log stream for module.

get-logical-host-property ((host object) (property object)) : [Command]

Lookup the value of property for the logical host host.

get-native-source-subdirectory-from-file-type

[Function]

((type KEYWORD)) : STRING

Compute a native source subdirectory that should be used for files of type. If type does not naturally suggest which native language it is associated with, key in on the current translation output language. Returns the empty string for unhandled types.

get-property ((property NAME) &rest (defaultValue OBJECT)) : [Command] OBJECT

Lookup property (a string or symbol) in the configuration table and return its value. If it is undefined, return the optional default Value. Note that property is evaluated and will need to be quoted if supplied as a symbol. Symbols will also be upcased if this command is run in a non-case- sensitive module.

- get-quoted-tree ((tree-name STRING) (modulename STRING)) : CONS [Function] Return the quoted tree with name tree-name.
- get-root-directory-from-file-extension ((file FILE-NAME)) : [Function] FILE-NAME

Given a file, determine which STELLA installation root directory tree it naturally belongs to based on its extension (i.e., source, native or binary).

- get-root-directory-from-file-type ((type KEYWORD)): STRING [Function] Given a normalized file type, determine which STELLA installation root directory tree it naturally belongs to (i.e., source, native or binary).
- get-slot ((self standard-object) (slot-name symbol)) : slot [Function] Return the slot named slot-name on the class representing the type of self.
- get-stella-class (class-name (error? BOOLEAN)) : [Method on Surrogate] CLASS

Return a class with name class-name. If none exists, break if error?, else return null.

- get-stella-class (class-name (error? BOOLEAN)): CLASS [Method on SYMBOL] Return a class with name class-name. If non exists, break if error?, else return null.
- get-stella-class (class-name (error? BOOLEAN)): CLASS [Method on STRING] Return a class with name class-name. If none exists, break if error?, else return null.
- get-system-definition ((name STRING) (error? BOOLEAN)): [Function]
 SYSTEM-DEFINITION

Return a system named *name*. If no such system is currently defined, look for a system definition file for *name* in standard locations and try to load it. If no matching system could be found or loaded and *error*? is true, raise an error, otherwise, simply return NULL.

get-system-last-modified-date ((system system-definition)) : [Function]

Compute a last-modified date for *system* based on its most recently modified source file.

get-system-subdirectory-from-file-type ((type KEYWORD)): [Function]
STRING

Compute a native system subdirectory that should be used for files of type. If type does not naturally suggest which native language it is associated with, key in on the current translation output language. Returns the empty string for unhandled types.

- get-system-version-string ((system SYSTEM-DEFINITION)): STRING [Function] Compute a version string for system which is either based on an explicit: version annotation on systems definition, the readable value of an existing *<system>-version[-string]*, variable or on its most recent modification date of any of its source files.
- get-temp-directory (): STRING [Function]

 Return a suitable directory for temporary files. Uses the value of stella.tempDirectory if defined; otherwise, it will use a suitable OS-

stella.tempDirectory if defined; otherwise, it will use a suitable OS-specific default. The returned directory will end in a separator for immediate concatenation with a physical filename.

get-time (date (timezone float)): INTEGER [Method on CALENDAR-DATE]
INTEGER INTEGER INTEGER

Returns multiple values of hours, minutes, seconds, milliseconds for the calendar date date in timezone. timezone is the number of hours added to UTC to get local time. It is in the range -12.0 to +14.0 where UTC is zone 0.0

get-token-float (): OBJECT [Macro]

User-level macro to access the most recently parsed token as a float. This assumes correct signed float syntax and only checks for overflows. The main benefit for this is that it doesn't generate strings and wrappers. Float parsing and conversion is generally hairy and we are probably not covering all special cases here; but we are fast:-)

get-token-integer (): OBJECT [Macro]
User-level macro to access the most recently parsed token as an integer. This assumes correct signed integer syntax and only checks for overflows.

get-token-long-integer (): OBJECT

[Macro]

User-level macro to access the most recently parsed token as a long integer. This assumes correct signed long-integer syntax and only checks for overflows.

- get-xml-base-attribute-value ((expression cons)): STRING [Function]
 Return the last base url attribute in the attribute list of this element if it exists.
 Otherwise NULL.
- getenv ((varname STRING) & rest (deflt STRING)): STRING [Command]

 Return the value of the OS environment variable varname. If it is not defined or if
 its value is the empty string and a deflt is provided, return the default value instead.

Return the type spec for the global variable global.

- hash-string ((string STRING) (seedCode INTEGER)): INTEGER [Function] Generate a hash-code for string and return it. Two strings that are equal but not eq will generate the same code. The hash-code is based on seedCode which usually will be 0. However, seedCode can also be used to supply the result of a previous hash operation to achieve hashing on sequences of strings without actually having to concatenate them.
- heap-root (self): (LIKE (ANY-VALUE SELF)) [Method on HEAP] Return the root of self (NULL if self is empty). The root contains the minimum element of a min-heap with < predicate.
- heapify (self): [Method on HEAP]
 Restore the heap property of self according to its predicate. Normally, this is not needed, since insert operations preserve the heap property. However, this can be useful after bulk insertion of values or if predicate has been changed.
- help-advance-past-whitespace ((source STRING) (start INTEGER) [Function] (end INTEGER)): INTEGER

 Helper for advance-past-whitespace that requires end to be properly set.

neiper for advance-past-whitespace that requires end to be properly set.

help-find-matching-prefix-length ((string1 STRING) [Function] (start1 INTEGER) (end1 INTEGER) (string2 STRING) (start2 INTEGER) (end2 INTEGER)): INTEGER

Helping function for find-matching-prefix that requires end1 and end2 to be properly set up.

Return the module located at *pathName*, or null if no such module exists. The search looks at ancestors and top-most (cardinal) modules. If *error*? is true, throw an exception if no module is found.

help-option-handler ((option CMD-LINE-OPTION) (value OBJECT)): [Function] Print documentation about all currently registered option handlers.

```
help-print-outline (top (stream OUTPUT-STREAM)
                                                               [Method on CLASS]
         (current-depth integer) (depth integer) (named? BOOLEAN)):
     Helper method for print-outline
help-print-outline (top (stream OUTPUT-STREAM)
                                                             [Method on OBJECT]
         (current-depth integer) (depth integer) (named? BOOLEAN)):
     Helper method for print-outline
help-print-outline (top (stream OUTPUT-STREAM)
                                                                [Method on SLOT]
         (current-depth integer) (depth integer) (named? BOOLEAN)):
     Helper method for print-outline
help-print-outline (top (stream OUTPUT-STREAM)
                                                             [Method on MODULE]
         (current-depth integer) (depth integer) (named? BOOLEAN)):
     Helper method for print-outline
help-print-outline (top (stream OUTPUT-STREAM)
                                                           [Method on CONTEXT]
         (current-depth integer) (depth integer) (named? BOOLEAN)):
     Helper method for print-outline
hex-character-value ((c CHARACTER)): INTEGER
                                                                       [Function]
     Convert the base-16 hex character c into a base-10 number.
                                                             [Method on OBJECT]
home-module (self): MODULE
     Return the home module of self.
if-output-language ((language KEYWORD) (thenForm OBJECT)
                                                                         [Macro]
         (elseForm object)): object
     Expand to thenForm if the current translator output language equals language. Oth-
     erwise, expand to elseForm. This can be used to conditionally translate Stella code.
if-stella-feature ((feature KEYWORD) (thenForm OBJECT)
                                                                         [Macro]
         (elseForm object)) : object
     Expand to thenForm if feature is a currently enabled STELLA environment feature.
     Otherwise, expand to elseForm. This can be used to conditionally translate Stella
     code.
ignore (&body (variables CONS)) : OBJECT
                                                                         [Macro]
     Ignore unused variables with NoOp setq statements.
```

incrementally-translate ((tree object)): object [Function]
Translate a single Stella expression tree and return the result. For C++ and Java print the translation to standard output and return NIL instead.

Helper function that indents outline printings for level *current-depth* on *stream* using the value of the global variable *OUTLINE-INDENT-STRING*

inform (&body (body CONS)): OBJECT [Macro]
Print informative message, placing non-string arguments in quotes, and terminating with a newline.

initial-value (self): OBJECT

[Method on CLASS]

Return an initial value for the class self.

initial-value (self): OBJECT

[Method on STORAGE-SLOT]

Return an initial value for *self*, or *null*. The initial value can be defined by the slot itself, inherited from an equivalent slot, or inherit from the :initial-value option for the class representing the type of *self*.

initialize-array (self

[Method on DIMENSIONAL-ARRAY-MIXIN]

(initialValue (LIKE (ANY-VALUE SELF)))):

Initialize the elements of self with initialValue.

initialize-hash-table (self):

[Method on Stella-Hash-Table]

Initialize the STELLA hash table *self*. This is a no-op and primarily exists to shadow the standard initializer inherited from ABSTRACT-HASH-TABLE. STELLA hash tables are initialized at the first insertion operation.

initially (self): OBJECT

[Method on STORAGE-SLOT]

Defines the value of a slot before it has been assigned a value.

insert (self

[Method on Custom-Vector-sequence]

(value (LIKE (ANY-VALUE SELF)))) :

Append value to the END of the sequence self. Resize the array if necessary.

insert (self (value (LIKE (ANY-VALUE SELF)))) :

[Method on HEAP]

Insert value into self and restore the heap property. Signal an error if there is no more room in self. Maintains self as a Min-heap if self's predicate has < semantics; otherwise as a Max-heap.

insert-if-better (self (value (LIKE (ANY-VALUE SELF)))): [Method on HEAP] Insert value into self and restore the heap property. If self has available room, simply

Insert value into self and restore the heap property. If self has available room, simply insert value. If the heap is full, only insert value if it is better than the current root (i.e., if value is greater than the minimum of self for the case of a min-heap where selfs predicate has < semantics). In that case, replace the root of self and restore the heap property. This is useful to build and maintain a heap with some top-N elements (relative to predicate) where the root (or minimum) of self is the currently weakest element at the end of the list.

int-to-string ((i INTEGER)): STRING

[Function]

Convert i to its string representation and return the result. This is a convenience function that expects regular integers as opposed to longs which is useful in contexts where we do automatic unwrapping based on the target.

integer-length ((x LONG-INTEGER)) : INTEGER

[Function]

Return the 1-based position of the left-most bit in x. If x is negative, we only count the value bits, not the sign.

integer-length10 ((x LONG-INTEGER)) : INTEGER

[Function]

Return the 1-based position of the left-most non-zero digit in the base-10 representation of x. If x is negative, we only consider its absolute value, not the sign. This effectively computes the minimum number of base-10 digits to represent x, with the exception of x=0.

integer-to-hex-string ((i LONG-INTEGER)): STRING [Function] Convert i to a string representation in hexadecimal notation and return the result.

integer-to-string-in-base ((i LONG-INTEGER) (base INTEGER)): [Function]

Convert i to a string representation in base and return the result. base must be positive and not more than 36.

Note that in the C++ version, only 8, 10 and 16 will work as *base* arguments, since that is all the underlying implementation supports. Other argument values will be treated as 10.

integer-valued? ((x FLOAT)): BOOLEAN [Function] Returns true if x is the floating point representation of an integer.

intern-stella-name ((name STRING)): GENERALIZED-SYMBOL [Function] Parse name which is assumed to be the printed representation of a STELLA symbol, surrogate or keyword, intern it into the current or specified module and return the result. This is identical to calling unstringify on name but 10-15 times faster.

isa? ((object OBJECT) (type TYPE)): BOOLEAN [Function]
Return true iff object is an instance of the class named type.

java-translate-system ((systemName STRING)): [Function]
Translate the system systemName to Java.

jptrans ((statement object)): [N-Command]
Translate statement to C++ and print the result.

keyword-name? ((name STRING)): BOOLEAN [Function]
Return TRUE if name is prefixed by:.

kvlist-to-plist ((self KEY-VALUE-LIST)): (PROPERTY-LIST OF (LIKE [Function] (ANY-KEY SELF)) (LIKE (ANY-VALUE SELF)))

Convert self into a property list with identical and identically ordered keys and values.

last (self): (LIKE (ANY-VALUE SELF)) [Method on VECTOR-SEQUENCE]
Return the last item in the vector self.

last (self): (LIKE (ANY-VALUE SELF)) [Method on HEAP] Return the last item in the heap self which will be the largest or best item if self is a sorted min-heap with a < predicate.

last (self): CHARACTER [Method on BUFFERED-STRING]
Return the last character in self.

length (self): INTEGER [Method on CONS-ITERATOR]
Iterate over self, and count how many items there are.

length (self): INTEGER

[Method on HEAP]

Return the length of the currently filled portion of self.

length (self): INTEGER

[Method on DIMENSIONAL-ARRAY-MIXIN]

Return the total number of elements in self.

length (self): INTEGER

[Method on 2-DIMENSIONAL-ARRAY-MIXIN]

Return the total number of elements in self.

length-setter (self (newLength integer)) : INTEGER

[Method on Buffered-String]

Reset the length of self to newLength. Fill in NULL characters if newLength is greater than the current length. This is the safe way to reset the fill pointer.

lispify ((thing UNKNOWN)): LISP-CODE

[Function]

Convert a Stella thing as much as possible into a Common-Lisp analogue. The currently supported thing types are CONS, LIST, KEY-VALUE-LIST, ITERATOR, SYMBOL, KEYWORD, and all wrapped and unwrapped literal types. BOOLEANs are translated into Lisp's CL:T and CL:NIL logic. Unsupported types are left unchanged.

lispify-boolean ((thing UNKNOWN)): LISP-CODE

[Function]

Lispify thing which is assumed to be a (possibly wrapped) Stella boolean.

list-directory-files ((directory STRING)): (CONS OF

[Command]

STRING-WRAPPER) Return all the files and sub-directories in directory sorted by name. Each returned

file is a bare file name without a directory component. If a file is a directory, it will look just like a plain file. This means consumers might have to explicitly test whether a file is a directory depending on what they do. Excludes . and .. directories. Handles logical pathnames but resulting files will always use physical pathname syntax. This is mostly consistent across native languages, but some differences still exist - e.g., Lisp will convert . or .. into absolute pathnames.

list-directory-files-recursively ((directory STRING)): (CONS [Command] OF STRING-WRAPPER)

Just like list-directory-files (which see) but also recurses into subdirectories. Files at the top level of directory will be bare file names without a directory component. Files in subdirectories will be prefixed with the relative subdirectory path starting right below directory. The sort order is lexicographic within directories which results in a depth-first presentation order of files.

list-modules ((kb-only? BOOLEAN)) : (CONS OF MODULE) [Command] Returns a cons of all modules defined in PowerLoom. If kb-only? is true, then any modules which are code only or just namespaces are not returned.

listify (self): (LIST OF (LIKE (ANY-VALUE SELF))) Return a list of elements in self.

[Method on CONS]

listify (self): (LIST OF (LIKE (ANY-VALUE SELF)))

[Method on LIST]

Return self.

listify (self): (LIST OF (LIKE (ANY-VALUE SELF)))

Return a list of key-value pairs in self.

[Method on KEY-VALUE-LIST]

listify (self): (LIST OF (LIKE (ANY-VALUE SELF)))
Return a list of elements in self.

[Method on VECTOR]

listify (self): (LIST OF (LIKE (ANY-VALUE SELF)))
Return a list of elements generated by self.

[Method on ITERATOR]

load-configuration-file ((file FILE-NAME)) :

[Command]

CONFIGURATION-TABLE

Read a configuration file and return its content as a configuration table. Also enter each property read into the global system configuration table. Assumes Java-style property file syntax. Each property name is represented as a wrapped string and each value as a wrapped string/integer/float or boolean.

load-file ((file STRING)) :

[Command]

Read STELLA commands from file and evaluate them. The file should begin with an in-module declaration that specifies the module within which all remaining commands are to be evaluated The remaining commands are evaluated one-by-one, applying the function evaluate to each of them.

[Function]

Load the file value using the STELLA load-file command.

[Function]

Modify the current file load path according to option and value.

load-system ((systemName STRING)

[Command]

&rest (language&options OBJECT)): BOOLEAN

Natively language-compile out-of-date translated files of system systemName (only supported for Lisp at the moment) and then load them into the running system. Return true if at least one file was compiled. The following keyword/value options are recognized:

- :language: can be used as an alternative to the optional language argument. If not specified, the language of the running implementation is assumed.
- :force-recompilation? (default false): if true, files will be compiled whether or not their compilations are up-to-date.
- :startup? (default true): if true, the system startup function will be called once all files have been loaded.
- :recursive? (default false): if true, perform load-system with the provided options on systemName as well as all its required systems and so on. Required systems will be processed first. Note that even without this option, any required systems that have not yet been loaded or started up will also be processed, since that is assumed when loading systemName and supporting modules from a definition file.
- :root-source-directory, :root-native-directory, :root-binary-directory: if specified these directories will be used to override the respective paths provided in system definitions or computed as defaults from a system's home location.

- log-level<= ((level OBJECT) (module STRING)): BOOLEAN [Function]
 Return TRUE if level is lower than or equal to the current log level of module. Return FALSE if any of them are undefined.
- log-message ((module STRING) (logLevel OBJECT) (message CONS)): [Function] Log all elements of message to modules log stream if logLevel is the same or lower than the modules log level. Interprets EOL or :EOL to print a line terminator.
- log2 ((n FLOAT)): FLOAT Return the logarithm (base 2) of n.

[Function]

logmsg ((module string) (logLevel object) & rest (message object)) [Function]

Log all elements of message to modules log stream if logLevel is the same or lower than the modules log level. Interprets EOL or :EOL to print a line terminator.

- lookup-class (name): CLASS [Method on SYMBOL]
 Return a class with name name. Scan all visible surrogates looking for one that has a class defined for it.
- lookup-class (name): CLASS [Method on STRING]
 Return a class with name name. Scan all visible surrogates looking for one that has a class defined for it.
- lookup-class-by-qualified-name ((qualifiedName STRING)): CLASS [Function] Variant of string.lookup-class that can specify a starting module through a qualifiedName.
- lookup-class-cpp-type-by-name ((qualifiedName STRING)): STRING [Function]
 Return a namespace-qualified C++ translation of the class type named by qualifiedName or NULL if no such STELLA class exists.
- lookup-command ((name SYMBOL)): METHOD-SLOT [Function] If name names an evaluable command return its associated command object; otherwise, return null. Currently, commands are not polymorphic, i.e., they can only be implemented by functions.
- lookup-command-like-function ((name SYMBOL)): METHOD-SLOT [Function] Look up a function with name that can be evaluated via apply just like a command, regardless of whether it was marked as such.
- lookup-configuration-property ((property STRING) [Function] (default Value OBJECT) (configuration CONFIGURATION-TABLE)): OBJECT Lookup property in configuration and return its value. Use the global system configuration table if configuration is NULL. Return default Value if property is not defined.
- lookup-configuration-property-values ((property STRING) [Function] (default Value object) (configuration configuration-table)): cons Lookup property in configuration, assume it is a multi-valued property and return its value(s) as a list. Use the global system configuration table if configuration is NULL. Return default Value if property is not defined or NIL is no default value is specified.

lookup-demon ((name STRING)) : DEMON

[Function]

Return the demon named name.

lookup-function ((functionSymbol symbol)) : FUNCTION

[Function]

Return the function defined for functionSymbol, if it exists.

lookup-function-by-name ((name STRING)): FUNCTION

[Function]

Return a function with name name visible from the current module. Scan all visible symbols looking for one that has a function defined for it.

lookup-function-by-qualified-name ((qualifiedName STRING)) : METHOD-SLOT

[Function]

Variant of lookup-function-by-name that can specify a starting module through a qualifiedName.

lookup-global-variable (self): GLOBAL-VARIABLE

[Method on SURROGATE]

Return a global variable with name self.

lookup-global-variable (self) :

[Method on GENERALIZED-SYMBOL]

GLOBAL-VARIABLE

Return a global variable with name self.

lookup-global-variable (self): GLOBAL-VARIABLE

[Method on STRING]

Return a global variable with name self.

lookup-global-variable-by-name ((name STRING)) :

[Function]

GLOBAL-VARIABLE

Return a global variable with *name* visible from the current module. Scan all visible symbols looking for one that has a global variable defined for it. NOTE: this is more robust than STRING.lookup-global-variable which will fail if there is a local symbol with *name* which shadows one higher up that is the name of a global.

lookup-global-variable-by-qualified-name

[Function]

((qualifiedName string)): Global-Variable

Variant of lookup-global-variable-by-name that can specify a starting module through a qualified Name.

lookup-local-slot ((class CLASS) (slot-name SYMBOL)) : SLOT Lookup a local slot with slot-name on class.

[Function]

lookup-logging-parameter ((module STRING) (parameter KEYWORD) [Function] (default object)): Object

Lookup logging parameter for module. Use default if no value is defined.

lookup-macro ((name SYMBOL)): METHOD-SLOT

[Function]

If name has a macro definition, return the method object holding its expander function.

lookup-slot ((class class) (slot-name symbol)) : slot

[Function]

Return a slot owned by the class class with name slot-name. Multiply inherited slots are disambiguated by a left-to-right class precedence order for classes with multiple parents (similar to CLOS).

lookup-slot-and-class-by-qualified-name

[Function]

((qualifiedname string)): Slot class

Lookup a slot via dotted notation with a possibly qualified class name. Examples: "cons.first" or "stella/cons.first". This is a variant of string-to-slot in describe.ste that actually obeys the class module if it is given. This also returns the specified class as a second value which might differ from the slot's owner class.

lookup-slot-by-qualified-name ((qualifiedname string)): SLOT [Function] Lookup a slot via dotted notation with a possibly qualified class name. Examples: "cons.first" or "stella/cons.first". This is a variant of string-to-slot in describe.ste that actually obeys the class module if it is given.

lookup-stella-name ((name STRING)): GENERALIZED-SYMBOL [Function]
Parse name which is assumed to be the printed representation of a STELLA symbol, surrogate or keyword, and try to look it up according to its type. This is a lookup version of intern-stella-name (which see) for cases where we don't necessarily want to create a symbol in case it doesn't exist already.

lookup-with-default (self

[Method on PROPERTY-LIST]

(key (like (any-key self))) (default (like (any-value self)))) : (like (any-value self))

Lookup key in self and return the result. Return default if no value was found.

lookup-with-default (self

[Method on KEY-VALUE-LIST]

(key (LIKE (ANY-KEY SELF))) (default (LIKE (ANY-VALUE SELF)))) : (LIKE (ANY-VALUE SELF))

Lookup key in self and return the result. Return default if no value was found.

lptrans ((statement OBJECT)) :

[N-Command]

Translate statement to Common-Lisp and print the result.

make-file-name ((filePath STRING) (type KEYWORD) (relative? BOOLEAN)): FILE-NAME

[Function]

Make an absolute file-name string from filePath with directory location and file extension determined by type and relative? type is the main determiner for whether we are creating a source, native or binary pathname in the respective root directories, and it also controls the new extension of the resulting pathname replacing any one on filePath. If relative? is TRUE, then the respective root directory prefix is appended, plus any additional relevant language, system and source subdirectories. If relative? is FALSE, then the current directory prefix of filePath as indicated by its extension is switched to the new root directory indicated by type. In this case, only the root and language directories are inserted, but all the remaining source directory components are left the same (thus, this will generally not do the right thing for Java file names). This function takes the dynamic state of currently active systems and modules into account.

make-matching-name ((original STRING) &rest (options OBJECT)): [Function]

Keyword options: :break-on-cap one of :YES :NO :CLEVER default is :CLEVER :break-on-number one of :YES :NO :CLEVER default is :CLEVER :break-on-separators string default is "-_ " :remove-prefix string :remove-suffix string

:case one of :UPCASE :TitleCase :titleCaseX :downcase :Capitalize :preserve default is :TitleCase :separator string default is "" :add-prefix string :add-suffix string

MAKE-MATCHING-NAME returns a matching name (a string) for the input name (a string). A matching name is constructed by breaking the input into words and then applying appropriate transforms. The arguments are used as follows: original is the input name. It is a string. :break-on-cap is a keyword controlling whether changes in capitalization is used to indicate word boundaries. If :YES, then all capitalization changes delineate words. If :CLEVER, then unbroken runs of capitalized letters are treated as acronyms and remain grouped. If :NO or NULL, there is no breaking of words based on capitalization. :break-on-number is a flag controlling whether encountering a number indicates a word boundary. If: YES, then each run of numbers is treated as a word separate from surrounding words. If :CLEVER, then an attempt is made to recognize ordinal numbers (ie, 101st) and treat them as separate words. If: NO or NULL, there is no breaking of words when numbers are encountered. :break-on-separators A string of characters which constitute word delimiters in the input word. This is used to determine how to break the name into individual words. Defaults are space, - and _. :remove-prefix Specifies a prefix or suffix that is stripped from the input remove-suffix name before any other processing. This allows the removal of any naming convention dictated prefixes or suffixes. :add-prefix Specifies a prefix or suffix that is added to the output name :add-suffix after all other processing. This allows the addition of any naming convention dictated prefixes or suffixes. :case The case of the resulting name. This is applied to the name before adding prefixes or suffixes. The two title case options differ only in how the first word of the name is treated. :TitleCase capitalizes the first letter of the first word and also the first letter of all other words. :TitleCaseX does not capitalizes the first letter of the first word but capitalizes the first letter of all subsequent words. :preserve results in no change in case. :separator This is a string specifying the word separator to use in the returned name. An empty string (the default) means that the resulting words are concatenated without any separation. This normally only makes sense when using one of the title case values for the case keyword.

```
make-matching-name-full ((originalname STRING) [Function]
(breakoncap KEYWORD) (breakonnumber KEYWORD)
(breakonseparators STRING) (removeprefix STRING) (removesuffix STRING)
(addprefix STRING) (addsuffix STRING) (outputcase KEYWORD)
(outputseparator STRING)): STRING
```

Non-keyword version of make-matching-name, which will probably be easier to use when called from non-Lisp languages.

make-system ((systemName STRING)

[Command]

&rest (language&options object)): BOOLEAN

Translate all out-of-date files of system systemName into language (the first optional argument of language&options) and then compile and load them (the latter is only possible for Lisp right now). The following keyword/value options are recognized:

- :language: can be used as an alternative to the optional language argument. If not specified, the language of the running implementation is assumed.
- :two-pass?: if true, all files will be scanned twice, once to load the signatures of objects defined in them, and once to actually translate the definitions. Otherwise, the translator will make one pass in the case that the system is already loaded (and is being remade), and two passes otherwise.
- :development-settings? (default false): if true translation will favor safe, readable and debuggable code over efficiency (according to the value of :development-settings on the system definition). If false, efficiency will be favored instead (according to the value of :production-settings on the system definition).
- :production-settings? (default true): inverse to :development-settings?.
- :force-translation? (default false): if true, files will be translated whether or not their translations are up-to-date.
- :force-recompilation? (default false): if true, translated files will be recompiled whether or not their compilations are up-to-date (only supported in Lisp right now).
- :load-system? (default true): if true, compiled files will be loaded into the current STELLA image (only supported in Lisp and Java right now).
- :startup? (default true): if true, the system startup function will be called once all files have been loaded.
- :recursive? (default false): if true, perform make-system with the provided options on systemName as well as all its required systems and so on. Required systems will be processed first. Note that even without this option, any required systems that have not yet been loaded or started up will also be processed, since that is assumed when loading systemName and supporting modules from a definition file.
- :root-source-directory, :root-native-directory, :root-binary-directory: if specified these directories will be used to override the respective paths provided in system definitions or computed as defaults from a system's home location.
- make-system-definition-file-name ((name STRING)): FILE-NAME [Function] Make a canonical system definition file name for a system named name.
- make-temporary-file ((prefix STRING) (suffix STRING)): STRING [Function] Variant of make-temporary-file-name that actually allocates the file to prevent other processes from using that name. This is still not fully thread safe for that we would need a file lock but maybe a bit better in avoiding collisions.
- $\max (x (y \text{ INTEGER})) : \text{INTEGER}$ [Method on INTEGER] Return the maximum of x and y. If either is NULL, return the other.
- max (x (y LONG-INTEGER)): LONG-INTEGER [Method on LONG-INTEGER]
 Return the maximum of x and y. If either is NULL, return the other.

 $\max (x (y \text{ FLOAT})) : \text{FLOAT}$ [Method on FLOAT] Return the maximum of x and y. If either is NULL, return the other.

- $\max (x (y \text{ NUMBER-WRAPPER})) : \text{NUMBER-WRAPPER} [Method on NUMBER-WRAPPER]}$ Return the maximum of x and y. If y is NULL, return x.
- member? (self (value object)): Boolean [Method on cons-iterator]

 Iterate over values of self and return TRUE if one of them is eq1? to 'value.
- $\begin{array}{ll} \textbf{member? (self (object \ \texttt{OBJECT)): BOOLEAN}} & [\textbf{Method on COLLECTION}] \\ \textbf{Return true iff } object \ \textbf{is a member of the collection } \textbf{self.} \end{array}$
- member? (self (value object)): Boolean [Method on sequence]
 Return TRUE if value is a member of the sequence self.
- memoize ((inputArgs cons) &body (body cons)): Object [Macro] Compute the value of an expression and memoize it relative to the values of inputArgs. inputArgs should characterize the complete set of values upon which the computation of the result depended. Calls to memoize should be of the form

(memoize ($\langle arg \rangle +$) {: $\langle option \rangle \langle value \rangle \}^* \langle expression \rangle$)

and have the status of an expression. The following options are supported:

:timestamps A single or list of keywords specifying the names of timestamps which when bumped should invalidate all entries currently memoized in this table. :name Names the memoization table so it can be shared by other memoization sites. By default, a gensymed name is used. CAUTION: IT IS ASSUMED THAT ALL ENTRIES IN A MEMOZATION TABLE DEPEND ON THE SAME NUMBER OF ARGUMENTS!! :max-values The maximum number of values to be memoized. Only the :max-values most recently used values will be kept in the memoization table, older values will be discarded and recomputed if needed. Without a :max-values specification, the memoization table will grow indefinitely.

PERFORMANCE NOTES: For most efficient lookup, input arguments that vary the most should be listed first. Also, arguments of type STANDARD-OBJECT (and all its subtypes) can be memoized more efficiently than arguments of type OBJECT or wrapped literals (with the exception of BOOLEANs).

merge-file-names ((baseFile file-name) (defaults file-name)): [Function] file-name

Parse baseFile, supply any missing components from defaults if supplied and return the result.

merge-null-fields (self [Method on DECODED-DATE-TIME] (default DECODED-DATE-TIME)):

Replace any null valued fields in *self* with values from *default*. The day of the week will be set consistently, if possible.

merge-superior-null-fields (self [Method on DECODED-DATE-TIME] (default DECODED-DATE-TIME)):

Replace only null valued fields in *self* that represent larger time units than the smallest non-null in *self* with values from *default*. The day of the week will be set consistently,

if possible. Example: if *self* just has the month being non-null, then only the year will be filled in from *default*. If the day and minute were non-null, then hour, month and year will be filled.

This can be useful when one doesn't want to extend the precision of the answer.

- min (x (y INTEGER)): INTEGER [Method on INTEGER] Return the minimum of x and y. If either is NULL, return the other.
- min (x (y LONG-INTEGER)): LONG-INTEGER [Method on LONG-INTEGER] Return the minimum of x and y. If either is NULL, return the other.
- min (x (y FLOAT)): FLOAT [Method on FLOAT] Return the minimum of x and y. If either is NULL, return the other.
- min (x (y NUMBER-WRAPPER)): NUMBER-WRAPPER [Method on NUMBER-WRAPPER] Return the minimum of x and y. If y is NULL, return x.
- mod (x (modulus integer)): integer [Method on integer]

 True modulus. Return the result of x mod modulo. Note: In C++ and Java, mod has more overhead than the similar function rem. The answers returned by mod and rem are only different when the signs of x and modulo are different.
- mod (x (modulus Long-integer)): Long-integer [Method on Long-integer]

 True modulus. Return the result of x mod modulo. Note: In C++ and Java, mod has
 more overhead than the similar function rem. The answers returned by mod and rem
 are only different when the signs of x and modulo are different.
- multiple-parents? (class): BOOLEAN [Method on CLASS]
 Return true if class has more than one direct superclass.
- multiple-parents? (module): BOOLEAN [Method on MODULE]
 Return TRUE if module has more than one parent.
- multiple-parents? (world): BOOLEAN [Method on WORLD] Return FALSE always, since worlds never have more than one parent.
- name-to-string ((name OBJECT)): STRING [Function]
 Return the string represented by name. Return null if name is undefined or does not represent a string.
- native-delete-file ((fileName file-name)): [Function] Delete the file fileName. This does not handle any necessary pathname translations or error conditions.
- native-file-length ((fileName file-name)): Long-integer [Function] Return the length of file fileName in bytes or NULL if that cannot be determined. This does not handle any necessary pathname translations or error conditions.
- native-file-write-date ((fileName FILE-NAME)): CALENDAR-DATE [Function] Return the time at which file fileName was last modified or NULL if that cannot be determined. This does not handle any necessary pathname translations or error conditions.

included in match.

native-probe-directory? ((fileName file-name)): BOOLEAN [Function] Return true if file fileName exists and is a directory. Note that this does not necessarily mean that the directory can also be read. This does not handle any necessary pathname translations or error conditions.

native-probe-file? ((fileName file-name)): Boolean [Function] Return true if file fileName exists. Note that this does not necessarily mean that the file can also be read. This does not handle any necessary pathname translations or error conditions.

native-read-line ((inputStream input-stream)): string [Function]
Read one line from inputStream using the native language readline algorithm and return the result. On EOF return null

native-rename-file ((fromFile file-NAME) (toFile file-NAME)): [Function] Rename the file fromFile to toFile. This does not handle any necessary pathname translations or error conditions.

next? (self): BOOLEAN [Method on MEMOIZABLE-ITERATOR]
Generate the next value of the memoized iterator self (or one of its clones) by either using one of the values generated so far or by generating and saving the next value of the base-iterator.

no-duplicates? (self): BOOLEAN [Method on COLLECTION]
Return true if the collection self forbids duplicate values.

non-empty? (x): BOOLEAN [Method on STRING-WRAPPER] Return true if x is not the wrapped empty string ""

non-empty? (self): BOOLEAN [Method on VECTOR-SEQUENCE]
Return true if self has length > 0.

non-empty? (self): BOOLEAN [Method on BUFFERED-STRING]
Return true if self has length > 0.

non-matching-position ((source STRING) (start INTEGER) [Function] (match STRING)): INTEGER

Returns the index into source, starting from start, of the first character that is not

non-matching-position-helper ((source STRING) (start INTEGER) [Function] (end INTEGER) (match STRING)): INTEGER
Helper for non-matching-position that requires end to not be null.

nth (self (position integer)): Character [Method on Buffered-String] Return the character in self at position.

nth (self (position integer)): (LIKE (ANY-VALUE [Method on NATIVE-VECTOR] SELF))

Return the element in self at position.

nth-setter (self (ch CHARACTER)

[Method on Buffered-String]

(position INTEGER)): CHARACTER Set the character in self at position to ch.

null? (x): BOOLEAN

[Method on LONG-INTEGER]

Return true if x is undefined (handled specially by all translators).

null? (x): BOOLEAN

[Method on ARRAY]

Return true if x is undefined (handled specially by all translators).

number-less-than? ((x NUMBER-WRAPPER) (y NUMBER-WRAPPER)): [Function]

Generic number comparison that works with integers, longs and floats.

object-equal? (x (y OBJECT)) : BOOLEAN

[Method on Vector-sequence]

Return TRUE iff the sequences x and y are structurally equivalent. Uses equal? to test equality of elements.

odd? (x): BOOLEAN

[Method on INTEGER]

Return true if x is an odd number.

odd? (x): BOOLEAN

[Method on LONG-INTEGER]

Return true if x is an odd number.

only-if ((test object) (expression object)): object

[Macro]

If test is TRUE, return the result of evaluating expression.

open-network-stream ((host STRING) (port INTEGER)) :

[Function]

INPUT-STREAM OUTPUT-STREAM

Open a TCP/IP network stream to *host* at *port* and return the result as an input/output stream pair.

ordered? (self): BOOLEAN

[Method on COLLECTION]

Return true if the collection self is ordered.

outline-depth-exceeded? ((current-depth INTEGER)

[Function]

(depth-limit integer)): BOOLEAN

Helper function that returns true if *current-depth* exceeds *depth-limit*. This functions uses the convention that a null or negative value of *depth-limit* means the depth is unlimited. In those cases it always returns false.

parameters (self): (LIST OF SYMBOL)

[Method on CLASS]

Returns the list of parameters names of self.

parse-date-time-in-time-zone ((date-time-string STRING)

[Function]

(time-zone float) (start integer) (end integer)

(error-on-mismatch? BOOLEAN)): DECODED-DATE-TIME

Tries very hard to make sense out of the argument date-time-string and returns a time structure if successful. If not, it returns null. If error-on-mismatch? is true, parse-date-time will signal an error instead of returning null. Default values are 00:00:00 in the given timezone on the current date. If the given time-zone value is null, then the local time zone for the given date and time will be used as determined by the operating system.

parse-date-time-relative-to-base ((date-time-string STRING) [Function] (base-date-time DECODED-DATE-TIME) (start INTEGER) (end INTEGER) (error-on-mismatch? BOOLEAN) (merge-null-fields? BOOLEAN)):

DECODED-DATE-TIME

Tries very hard to make sense out of the argument date-time-string and returns a time structure if successful. If not, it returns null. If error-on-mismatch? is true, parse-date-time will signal an error instead of returning null. Default values are passed in via base-date-time. If the timezone field that is passed in is NULL, then the local time zone for the parsed date/time will be used. If merge-null-fields? is true, then default values from base-time-date will be merged into missing components. If false, then they won't be merged in for null components but can still be used as a basis for interpretatation of relative time strings like "now" or "yesterday"

parse-float ((value STRING)) : FLOAT

[Function]

Convert a float value string into a float. Leading and trailing whitespace is allowed. Raise an error if we have illegal number syntax which makes it preferable over the naive C++ stringToFloat conversion function which just returns 0.

parse-integer ((value STRING)) : INTEGER

[Function]

Convert an integer value string into an integer. Leading and trailing whitespace is allowed. Raise an error if we have illegal number syntax which makes it preferable over the naive C++ stringToInteger conversion function which just returns 0.

parse-long-integer ((value STRING)) : LONG-INTEGER

[Function]

Convert a long integer value string into a long integer. Leading and trailing whitespace is allowed. Raise an error if we have illegal number syntax which makes it preferable over the naive C++ stringToInteger conversion function which just returns 0.

parse-options ((options object) (legalOptions&Types cons) [Function]

(coercionError? BOOLEAN) (allowOtherKeys? BOOLEAN)): PROPERTY-LIST Parse options, check their validity according to legalOptions&Types and return the result as a PROPERTY-LIST. legalOptions&Types has to either be NULL or a flat list of legal <keyword> <coercionType> pairs. A type specification of @IDENTITY means don't perform any coercion. If coercionError? is TRUE, raise an error if a coercion failed. If allowOtherKeys? is TRUE options other than those specified in legalOptions&Types are allowed but won't be coerced since we don't know their type. A special implicit :options keyword that does not need to be declared can be used to pass in an already parsed options list from a caller, which will then be analyzed and used instead.

parse-stella-name ((name STRING)

[Function]

(enableCaseConversion? boolean)): String String Keyword

Parse the printed representation name of a STELLA symbol, surrogate or keyword and return its symbol name, module name and type (which is either :SYMBOL, :SURROGATE or :KEYWORD). name can be qualified and must use the exact same syntax and escape characters that would be used if it were to be read by read-s-expression-from-string (or unstringify). If enableCaseConversion? is TRUE, the returned symbol name will be upcased if the current module is case-insensitive; otherwise, it will be returned as is. Raises a read exception if name does not represent

a symbol. This function is available primarily for efficiency, since it is about 10-15 times faster than unstringify.

pick-hash-table-size-prime ((minSize INTEGER)): INTEGER Return a hash table prime of at least minSize.

[Function]

plist-to-kvlist ((self property-list)): (Key-value-list of (like [Function] (Any-key self)) (like (any-value self)))

Convert self into a key-value list with identical and identically ordered keys and values.

plus? (x): BOOLEAN

[Method on INTEGER]

Return true if x is greater than 0.

plus? (x): BOOLEAN

[Method on LONG-INTEGER]

Return true if x is greater than 0.

pop-load-path () : STRING

[Command]

Remove the first element from the STELLA load path and return the removed element.

primary-type (self): TYPE

[Method on OBJECT]

Returns the primary type of *self*. Gets defined automatically for every non-abstract subclass of OBJECT.

primitive? (self): BOOLEAN

[Method on RELATION]

Return true if self is not a defined relation.

print (&body (body cons)) : OBJECT

[Macro]

Print arguments to the standard output stream.

print-configuration-properties

[Function]

((configuration configuration-table) (stream output-stream)):

Print all properties defined in configuration to stream.

print-exception-context ((e NATIVE-EXCEPTION)

[Function]

(stream output-stream)):

Prints system dependent information about the context of the specified exception e. For example, in Java it prints a stack trace. In Lisp, it is vendor dependent.

print-outline ((thing OBJECT) (stream OUTPUT-STREAM)

[Command]

(depth integer) (named? Boolean)):

Print an outline of thing and its subparts on stream. If depth is non-negative, only depth levels will be printed. If named? is TRUE, then only named entities will be printed.

This function is intended to be used on things like modules, contexts, concepts, etc. that have hierarchical structure. If *thing* doesn't have a hierarchical structure, it will just be printed.

print-properties ():

[Command]

Print all current configuration property information to standard output.

print-recycle-lists () :

[Function]

Print the current state of all recycle lists.

print-spaces (&body (body CONS)) : OBJECT

[Macro]

(print-spaces [stream] N) prints N spaces onto stream. If no stream form is provided, then STANDARD-OUTPUT will be used.

print-stella-features () :

[Command]

Print the list of enabled and disabled STELLA features.

print-unbound-surrogates (&rest (args OBJECT)) :

[N-Command]

Print all unbound surrogates visible from the module named by the first argument (a symbol or string). Look at all modules if no module name or null was supplied. If the second argument is true, only consider surrogates interned in the specified module.

print-undefined-methods ((module MODULE) (local? BOOLEAN)): [Function] Print all declared but not yet defined functions and methods in module. If local? is true, do not consider any parent modules of module. If module is NULL, look at all modules in the system. This is handy to pinpoint forward declarations that haven't been followed up by actual definitions.

print-undefined-super-classes ((class NAME)) :

[N-Command]

Print all undefined or bad (indirect) super classes of class.

private-class-methods ((class CLASS)) : (ITERATOR OF METHOD-SLOT)

[Function]

Iterate over all private methods attached to class.

private-class-storage-slots ((class CLASS)) : (ITERATOR OF STORAGE-SLOT)

[Function]

Iterate over all private storage-slots attached to class.

private? (self) : BOOLEAN

[Method on RELATION]

Return true if self is not public.

probe-directory? ((fileName FILE-NAME)) : BOOLEAN

[Function]

Return true if file *fileName* exists and is a directory. Note that this does not necessarily mean that the directory can also be read.

process-command-line-arguments ((count INTEGER)

[Function]

(arguments (ARRAY () OF STRING)) (unhandledOptionAction KEYWORD)): Interpret any command line arguments for which handlers have been registered. Leave any remaining unprocessed arguments in *unprocessed-command-line-arguments*. If any unprocessed arguments use option syntax (that is they start with a -), proceed according to unhandledOptionAction which can be one of :ignore, :warn or :error. This ensures that at any point in the option processing, *unprocessed-command-line-arguments* accurately reflects the arguments which have been either skipped or not handled yet.

process-doctype ((doctype-declaration CONS)): XML-DOCTYPE [Function]
Takes an S-Expression representing a doctype and processes into a DOCTYPE object.

ptrans ((statement object)) :

[N-Command]

Translate statement to Common-Lisp and print the result.

public-class-methods ((class class)): (ITERATOR OF METHOD-SLOT) [Function] Iterate over all private methods attached to class.

public-class-storage-slots ((class CLASS)) : (ITERATOR OF STORAGE-SLOT)

[Function]

Iterate over all public storage-slots attached to class.

public-slots (self): (ITERATOR OF SLOT)

Return an iterator over public slots of self.

[Method on CLASS]

public-slots (self): (ITERATOR OF SLOT)
Return an iterator over public slots of self.

[Method on OBJECT]

public? (self): BOOLEAN

[Method on SLOT]

True if self or one it its ancestors is marked public.

push-load-path ((path STRING)): (CONS OF STRING-WRAPPER) [Command]

Add the directories listed in the |-separated path to the front of the STELLA load path. Return the resulting load path.

pushf ((place cons) (value object)): object Push value onto the cons list place. [Macro]

put-slot-value ((self STANDARD-OBJECT) (slot STORAGE-SLOT) (value OBJECT)): OBJECT

[Function]

Set or insert value for the slot slot on self. CAUTION: Assumes that collection-valued slots are non-null.

 $\verb"qualified-stella-name?" ((name \verb"string")) : \verb"BOOLEAN" \\$

[Function]

Return TRUE if *name* is a symbol or surrogate qualified with a module pathname or a module pathname ending with a /. Assumes that *name* is the printed representation of a STELLA symbol (potentially containing escape characters).

read-global-variable-value ((variable GLOBAL-VARIABLE)) : [Function]
OBJECT

Interpreted global variable reader which reads and returns its native value which will be wrapped if necessary. This will access the value at the top of the special stack.

read-line2 ((stream INPUT-STREAM)) : STRING KEYWORD

|Function

Read one line from *stream* and return the result and a keyword that indicates the terminator for that line ending: :CR:LF:CRLF or:EOF. This is not platform-dependent and differs from read-line by returning a second value. It may hang when used on interactive streams such as terminal or network streams with only CR line endings. It should only be used on file or string input streams.

read-native-variable-value ((var NATIVE-OBJECT-POINTER) [Function] (type TYPE)): OBJECT

Interpreted variable reader which reads a native code variable represented by var of type type and returns its value which will be wrapped if necessary. If var is a special

variable, this will access the current dynamic value at the top of the special stack. This relies upon *type* being completely accurate and bad things will happen if it is not.

read-slot-value ((self STANDARD-OBJECT) (slot STORAGE-SLOT)): [Function]

Read and return a (possibly wrapped) value for the slot slot on self.

read-xml-expressions ((filename STRING)): CONS [Function]
Read all of the top-level XML expressions from filename and return them in a list.

reader (self): SYMBOL [Method on STORAGE-SLOT]

Name of a method called to read the value of the slot self.

register-cmd-line-option (&rest (options OBJECT)): [Function] Register a command line option. :key identifies the name of the option which will usually start with a dash such as -e or --eval. :key2 and :key3 can be used to supply additional options (e.g., long option formats). To supply even more keys, a list can be supplied with the keys option. If a property is supplied, this option simply sets or adds to the values of the specified system configuration property. If a :handler name is specified, its function will be used to interpret the values of the option. documentation can be used to supply a documentation string which will be printed: by the help-option-handler (usually bound to -?). :value-type describes what type an option value should be coerced to before assigning it to the specified configuration property. :n-arguments describes how many arguments this option takes. This will be 0 for simple switches and can be 1 or greater than one for option handlers that need one or more arguments. :default-value defines the value to use for zero-argument :property options. If :multi-valued? is true, values of multiple occurrences of the option will be added to the specified configuration :property. :error-action can be one of ignore, warn or error to specify what to do in case an error is encountered during option processing.

register-property-demon ((property STRING) [Function] (demonName SYMBOL)):

Register the function named *demonName* as the demon for *property*. Demons will be run as after demons on every configuration table update. Set the property stella.test.propertyDemon to see a test demon in action.

regular-integer-valued? ((x LONG-INTEGER)): BOOLEAN [Function] Return true if x can be represented by a regular integer.

relative-unlogicalize-pathname ((pathName STRING)): STRING [Function] If pathName is a logical pathname translate it, however, remove the :root-directory prefix of the logical host. Otherwise, return pathName as is.

rem (x (y INTEGER)): INTEGER [Method on INTEGER]
Return the remainder from dividing x by y. The sign of the result is always the same as the sign of x. This has slightly different behavior than the mod function, and has less overhead in C++ and Java, which don't have direct support for a true modulus function.

buffer will be truncated.

rem (x (y LONG-INTEGER)): LONG-INTEGER [Method on LONG-INTEGER]
Return the remainder from dividing x by y. The sign of the result is always the same as the sign of x. This has slightly different behavior than the mod function, and has less overhead in C++ and Java, which don't have direct support for a true modulus function.

remove-configuration-property ((property STRING) (value OBJECT) [Function] (configuration CONFIGURATION-TABLE)): OBJECT

Remove value from property in configuration and return it. Use the global system configuration table if configuration is NULL.

- remove-duplicates (self): (LIKE SELF) [Method on COLLECTION]
 Return self with duplicates removed. Preserves the original order of the remaining members.
- remove-duplicates-equal (self): (LIKE SELF) [Method on CONS] remove-duplicates (which see) using an equal? test. IMPORTANT: since this uses hashing to speed things up, an equal-hash-code method needs to be defined for this to work.
- remove-duplicates-equal (self): (LIKE SELF) [Method on LIST] remove-duplicates (which see) using an equal? test.
- replace-heap-root (self (value (LIKE (ANY-VALUE SELF)))): [Method on HEAP] Replace the current root of self with value and restore the heap property. Signal an error if self is empty. Maintains self as a Min-heap if self's predicate has < semantics; otherwise as a Max-heap.
- required-slots (self): (LIST OF SYMBOL) [Method on CLASS]

 Returns a list of names of required slots for self.
- required? (self): BOOLEAN [Method on STORAGE-SLOT]

 True if a value must be assigned to this slot at creation time.
- reset (self): [Method on CROSS-PRODUCT-ITERATOR]
 Reset self to its initially allocated state. Note, that this is somewhat expensive, costing almost as much as allocating the iterator.
- reset-stella-features (): [Command]
 Reset STELLA features to their default settings.
- resize-buffer (self (size integer)): [Method on Buffered-String]

 MUTABLE-STRING

 Change the size of self to size. If size is smaller than the current size of self, it's
- reverse (self): (LIKE SELF) [Method on VECTOR-SEQUENCE] Reverse the order of elements in the active portion of self.
- reverse-interval ((lowerbound integer) (upperbound integer)): [Function]
 REVERSE-INTEGER-INTERVAL-ITERATOR
 Create a reverse interval object.

root-binary-directory () : FILE-NAME

[Function]

Accessor to determine the currently active binary directory root. If it is defined as an option in the currently active system action, use that. If we have an active system, use its value, otherwise use the STELLA default value.

root-native-directory () : FILE-NAME

[Function]

Accessor to determine the currently active native directory root. If it is defined as an option in the currently active system action, use that. If we have an active system, use its value, otherwise use the STELLA default value.

root-source-directory () : FILE-NAME

[Function]

Accessor to determine the currently active sources directory root. If it is defined as an option in the currently active system action, use that. If we have an active system, use its value, otherwise use the STELLA default value.

run-hooks ((hooklist hook-list) (argument object)):

[Function]

Run all hook functions in *hooklist*, applying each one to argument.

running-as-lisp? (): BOOLEAN

[Function]

Return true if the executable code is a Common Lisp application.

running-in-language (): KEYWORD

[Function]

Returns the keyword for the language the current implementation is running in.

running-system-information (): STRING

[Function]

Returns an information string about the current running system environment.

safe-compare-strings ((x STRING) (y STRING) (collation KEYWORD)) [Function]: INTEGER

Variant of compare-strings that also tolerates NULL values. NULL sorts after everything else in any collation.

safe-equal-hash-code ((self object)) : INTEGER

[Function]

Return a hash code for *self*. Just like equal-hash-code - which see, but also works for NULL. equal-hash-code methods that expect to handle NULL components should use this function for recursive calls.

safe-hash-code ((self OBJECT)) : INTEGER

[Function]

Return a hash code for self. Just like hash-code - which see, but also works for NULL.

 ${\tt safe-lookup-slot}$ ((class CLASS) (slot-name SYMBOL)) : ${\tt SLOT}$

[Function]

Alias for lookup-slot. Kept for backwards compatibility.

safety ((level integer-wrapper) (test object) &body (body cons)):

[Macro]

Signal warning message, placing non-string arguments in quotes.

save-configuration-file ((table CONFIGURATION-TABLE)

[Function]

(file file-name) (title string)):

Save table as a configuration file. Uses a Java-style property file syntax.

Save value to stream as a properly formatted configuration value.

search-cons-tree-with-filter? ((tree OBJECT) (value OBJECT) [Function] (filter CONS)): BOOLEAN

Return true iff the value value is embedded within the cons tree tree. Uses an eq1? test. Does not descend into any cons whose first element matches an element of filter.

search-for-object ((self object) (typeref object)): object [Function]
If self is a string or a symbol, search for an object named self of type type. Otherwise, if self is an object, return it.

seed-random-number-generator () :

[Function]

Seeds the random number generator based on the current time.

seed-random-number-generator2 () :

[Function]

Seeds the random number generator based on the current time and /dev/random if it is available.

sequence ((collectiontype TYPE) &rest (values OBJECT)) : (SEQUENCE [Function] OF OBJECT)

Return a sequence containing values, in order.

set-call-log-break-point ((count INTEGER)):

[Command]

Set a call log break point to *count*. Execution will be interrupted right at the entry of the *count*th logged function call.

set-configuration-property ((property STRING) (value OBJECT) (configuration CONFIGURATION-TABLE)): OBJECT [Function]

Set property in configuration to value and return it. Use the global system configuration table if configuration is NULL.

set-current-date (values-structure): [Method on DECODED-DATE-TIME]
Sets the current date into values-structure

set-current-date-time (values-structure): [Method on DECODED-DATE-TIME]
Sets the current date and time into values-structure

set-current-time (values-structure): [Method on DECODED-DATE-TIME]
Sets the current time into values-structure

set-load-path ((path STRING)): (CONS OF STRING-WRAPPER) [Command] Set the STELLA load path to the |-separated directories listed in path. Return the resulting load path.

set-log-level ((module STRING) (level OBJECT)): [Command]
Set the log-level for module to level. This is a convenience function for this common operation.

set-logging-parameters ((module STRING) &rest (params&values OBJECT)):

[Command]

Set logging parameters for *module*. The supported parameters are: :LOG-LEVELS - a cons list of legal levels in ascending log level order; for example, (:NONE :LOW :MEDIUM :HIGH) or (0 1 2 3). :LEVEL - the current log level for *module* :STREAM - the stream or file to log to (defaults to STANDARD-OUTPUT) :PREFIX - the prefix to use to identify the module (defaults to *module*) :MAX-WIDTH - logging output lines will be kept to approximately this width (defaults to 10000, minimum width of about 30 is used to print line header information).

[Function]

Set optimization levels for the qualities safety, debug, speed, and space.

set-property ((property NAME) (value OBJECT)) :

[Command]

Set property (a string or symbol) in the configuration table to value. Note that property is evaluated and will need to be quoted if supplied as a symbol. Symbols will also be upcased if this command is run in a non-case-sensitive module.

set-stella-feature (&rest (features KEYWORD)) :

[Command]

[Command]

Enable all listed STELLA features.

Set output language to new-language. Return previous language.

setq? ((variable symbol) (expression cons)) : OBJECT

[Macro]

Assign variable the result of evaluating expression, and return TRUE if expression is not NULL else return FALSE.

shadowed-symbol? ((symbol GENERALIZED-SYMBOL)): BOOLEAN Return true if symbol is shadowed in its home module.

[Function]

shift-right (arg (count integer)): integer [Method on integer]
Shift arg to the right by count positions and 0-extend from the left if arg is positive or 1-extend if it is negative. This is an arithmetic shift that preserve the sign of arg and is equivalent to dividing arg by 2** count.

shift-right (arg (count integer)): Long-integer [Method on Long-integer] Shift arg to the right by count positions and 0-extend from the left if arg is positive or 1-extend if it is negative. This is an arithmetic shift that preserve the sign of arg and is equivalent to dividing arg by 2** count.

signal ((type SYMBOL) &body (body CONS)): OBJECT Signal error message, placing non-string arguments in quotes.

[Macro]

orginal error message, placing non-suring arguments in quotes.

signal-read-error (&body (body CONS)) : OBJECT

[Macro]

Specialized version of signal that throws a READ-EXCEPTION.

Perform a destructive sort of *self* according to *predicate*, and return the result. If *predicate* has a < semantics, the result will be in ascending order. If *predicate* is null, a suitable < predicate is chosen depending on the first element of *self*, and it is assumed that all elements of *self* have the same type (supported element types are GENERALIZED-SYMBOL, STRING, INTEGER, and FLOAT).

sort (self (predicate function-code)): (HEAP OF (LIKE [Method on HEAP] (ANY-VALUE SELF)))

Sort the heap self according to predicate (in ascending order if predicate has < semantics). If predicate is NULL simply use selfs internal predicate (the normal case). If it is different from selfs internal predicate, heapify self first according to the new predicate, store the new predicate in self and then sort the heap. Note that a sorted array automatically satisfies the heap property. This is slightly different than a regular heap sort due to the way HEAP's are maintained; however, the complexity is the same.

Just like **sort** but assumes each element of *self* has a *slot* whose value will be used for comparison. Elements must be descendants of STANDARD OBJECT. Note that while this will work with literal-valued slots, it will cause value wrapping everytime *slot* is read.

Just like **sort** but assumes each element of *self* has a *slot* whose value will be used for comparison. Elements must be descendants of STANDARD OBJECT. Note that while this will work with literal-valued slots, it will cause value wrapping everytime *slot* is read.

Just like **sort** but assumes each element of *self* is a tuple (a cons) whose n-th element (0-based) will be used for comparison.

Split input into separate strings based on the separator character.

start-function-call-logging ((fileName STRING)): [Command]
Start function call logging to fileName.

starts-with? ((string STRING) (prefix STRING) (start INTEGER)): [Function]
BOOLEAN

Return TRUE if string starts with prefix starting from start (which defaults to 0 if it is supplied as NULL).

stella-collection? ((self OBJECT)): BOOLEAN Return true if self is a native collection.

[Function]

stella-information (): STRING

[Command]

Returns information about the current Stella implementation. Useful when reporting problems.

stella-integer-to-string-in-base ((integer LONG-INTEGER) (base INTEGER)): STRING

[Function]

STELLA version of integer-to-string-in-base which is faster than the C++ version we have but slower than the native Java version.

stella-object? ((self OBJECT)) : BOOLEAN

[Function]

Return true if self is a member of the STELLA class OBJECT.

stella-version-string (): STRING

[Function]

Return a string identifying the current version of STELLA.

stellafy ((thing LISP-CODE) (target Type TYPE)): OBJECT [Function]
Partial inverse to lispify. Convert the Lisp object thing into a Stella analogue of
type target Type. Note: See also stellify. it is similar, but guesses target Type on
its own, and makes somewhat different translations.

stellify ((self object)) : object

[Function]

Convert a Lisp object into a STELLA object.

stop-function-call-logging ():

[Command]

Stop function call logging and close the current log file.

stream-position (self): LONG-INTEGER [Method on OUTPUT-FILE-STREAM]
Return the current position of the file input cursor in self.

stream-position (self): LONG-INTEGER [Method on INPUT-FILE-STREAM]
Return the current position of the file input cursor in self.

stream-position-setter (self

[Method on Output-File-Stream]

(newpos Long-integer)): Long-integer

Set the current position of the file input cursor in self to newpos.

stream-position-setter (self

[Method on INPUT-FILE-STREAM]

(newpos Long-integer)): Long-integer

Set the current position of the file input cursor in *self* to *newpos*. If *self* has any tokenizer state associated with it, this will also reset to the start state of the tokenizer table; otherwise, behavior would be unpredictable unless the character class of the new position is exactly the same as the one following the most recent token.

stream-to-string (from): STRING

[Method on Input-Stream]

Read all of the input from stream and return it as a string.

Compare x and y and return -1, 0, or 1, depending on whether x is less than, equal, or greater than y relative to the :ascii-case-normalized collation. In this collation a < A < b which gives strings that only differ in case a definite order while otherwise behaving identically to :ascii-case-insensitive. This is similar to using a Java Collator for Locale.US with strength set to TERTIARY (which see).

string-search-ignore-case ((string STRING) (substring STRING) [Function] (start INTEGER)): INTEGER

Return start position of the left-most occurrence of *substring* in *string*, beginning from *start*. Return NULL if it is not a substring. The comparison ignores differences in letter case.

string-to-calendar-date-with-default ((input-date STRING) [Function] (default-date DECODED-DATE-TIME)): CALENDAR-DATE

Returns a calendar date object representing the date and time parsed from the *input-date* string. Default values for missing fields and the interpretation of relative references come from *default-date*. If the *default-date* is null, the current date will be used. If a null set of defaults is desired, use *NULL-DECODED-DATE-TIME*. If no valid parse is found, null is returned.

string-to-decoded-date-time ((input STRING)) : [Function]

Returns a decoded date-time object representing the date and time parsed from the *input* string. If no valid parse is found, null is returned.

string-to-int ((string STRING)): INTEGER [Function] Convert a string representation of an integer into an integer. This is a convenience

Convert a *string* representation of an integer into an integer. This is a convenience function that ensures a regular integer return value. If *string* represents a long integer, the behavior is undefined. Use parse-integer if the syntax of *string* needs to be checked for errors.

string-to-surrogate ((self STRING)): SURROGATE [Function] Return a surrogate with the name self visible in the current module. Very tricky: The logic is designed to avoid returning an inherited surrogate that has no value. In that case, a new local surrogate is created that shadows the inherited surrogate.

string-to-time-duration ((duration STRING)): TIME-DURATION [Function]
Parses and returns an time-duration object corresponding to duration. The syntax for
time duration strings is "{plus|minus} N days[; M ms]" where N and M are integer
values for days and milliseconds. If no valid parse is found, null is returned.

string-trim ((string STRING)): STRING [Function] Remove any leading and trailing white space from string and return a copy of the trimmed substring (which might be empty if we had all white space). If no white space was removed, string is returned unmodified and uncopied.

subclass-of? ((subClass class) (superClass class)): BOOLEAN [Function] Return true if subClass is a subclass of superClass.

subsequence (self (start integer) (end integer)) [Method on Buffered-string]
: string

Return a substring of **string** beginning at position *start* and ending up to but not including position *end*, counting from zero. An *end* value of NULL stands for the rest of the string.

subsequence (string (start integer)

[Method on MUTABLE-STRING]

(end integer)): string

Return a substring of *string* beginning at position *start* and ending up to but not including position *end*, counting from zero. An *end* value of NULL stands for the rest of the string.

substitute-characters (self (new-chars STRING)

[Method on STRING]

(old-chars string)): string

Substitute all occurrences of of a member of *old-chars* with the corresponding member of *new-chars* in the string *self*. Returns a new string.

Substitute all occurrences of of a member of old-chars with the corresponding member of new-chars in the string self. IMPORTANT: The return value should be used instead of relying on destructive substitution, since the substitution will not be destructive in all translated languages.

subtype-of? ((sub-type TYPE) (super-type TYPE)): BOOLEAN [Function]
Return true iff the class named sub-type is a subclass of the class named super-type.

super-classes (self): (ITERATOR OF CLASS)

[Method on CLASS]

Returns an iterator that generates all proper super classes of self.

surrogate-name? ((name STRING)) : BOOLEAN

[Function]

Return TRUE if name is prefixed by SURROGATE-PREFIX-CHARACTER.

surrogatify (self): SURROGATE

[Method on SURROGATE]

Converts self into a surrogate.

surrogatify (self): SURROGATE

[Method on SYMBOL]

Converts self into a surrogate (same semantics as symbol-to-surrogate which see).

surrogatify (self) : SURROGATE

[Method on STRING]

Converts self into a surrogate.

sweep (self):

[Method on OBJECT]

Default method. Sweep up all self-type objects.

symbol-to-surrogate ((self SYMBOL)) : SURROGATE

[Function]

Return a surrogate with the same name as *self*. Very tricky: The logic is designed to avoid returning an inherited surrogate that has no value. In that case, a new local surrogate is created that shadows the inherited surrogate. Unlike string-to-surrogate, the search starts first from the home context of *self*, and if that fails, then it restarts in *module*.

symbol-to-type ((self SYMBOL)) : SURROGATE

[Function]

Convert self into a surrogate with the same name and module.

system-default-value (self) : OBJECT

[Method on STORAGE-SLOT]

Return a default value expression, or if *self* has dynamic storage, an initial value expression.

system-default-value (self): OBJECT

[Method on SLOT]

Return a default value expression, or if *self* has dynamic storage, an initial value expression.

system-loaded-or-started-up? ((name STRING)): BOOLEAN

[Function]

Return true if system name has either been loaded or initialized with its startup function.

system-loaded? ((name STRING)) : BOOLEAN

[Function]

Return true if system name has been loaded.

terminate-program ():

[Command]

Terminate and exit the program with normal exit code.

test-property-demon ((action KEYWORD) (property STRING) (value OBJECT) (table CONFIGURATION-TABLE)):

[Function]

A test demon for the property demon machinery which simply prints arguments.

the-string (self): STRING

[Method on Buffered-String]

Return a substring of string beginning at position start and ending up to but not including position end, counting from zero. An end value of NULL stands for the rest of the string.

time-duration-to-string (date): STRING

[Method on TIME-DURATION]

Returns a string representation of date

time-zone-format60 ((timezone FLOAT) (include-colon? BOOLEAN)): [Function]

Format zone as an hh:mm or hhmm string depending on include-colon?

(quotechars string) (escapechars string)): (cons of cons)

toggle-output-language (): KEYWORD

[Function]

Switch between Common Lisp and C++ as output languages.

tokenize-string ((string STRING) (punctuationchars STRING)

[Function]

Simple tokenizer that is somewhere between Java's StringTokenizer and StreamTokenizer in functionality. It doens't specially support number tokens nor comment strings/sequences even though this could be added at the expense of some extra complexity. Returns a list of (<token-string> <token-type>) pairs, where the token type

is one of :TEXT, :PUNCTUATION or :QUOTE, i.e., all white space is ignored and escape characters are handled and removed. For example:

(tokenize-string "for(i='fo^'o'; i>0; i++)" "()=<>+-;" "'" "^") =>

```
(("for" :TEXT) ("(" :PUNCTUATION) ("i" :TEXT)
  ("=" :PUNCTUATION) ("'" :QUOTE) ("fo'o" :TEXT)
  ("'" :QUOTE) (";" :PUNCTUATION) ("i" :TEXT)
  (">" :PUNCTUATION) ("O" :TEXT) (";" :PUNCTUATION)
  ("i" :TEXT) ("++)" :PUNCTUATION))
```

NOTE: this aggregates multiple punctuation characters that immediately follow each other into a single token which is (generally) useful to pickup multi-character operators such as ++, >=, etc. It's still easy to pick them apart in a post-processing step if necessary (e.g., for the ++) case above), so we leave this for now as a feature.

```
top-level-stella-system-directory? ((directory FILE-NAME)): [Function]
```

Return TRUE if *directory* is a top-level STELLA installation directory containing one or more STELLA systems. We currently determine this solely by looking for the existence of at least one relevant top-level native directory. This is needed to find system root directories and other relevant STELLA installation directories.

```
trace-if ((keyword object) &body (body cons)): object [Macro]

If keyword is a trace keyword that has been enabled with add-trace print all the elements in body to standard output. Otherwise, do nothing. keyword can also be a list of keywords in which case printing is done if one or more of them are trace
```

```
translate-system ((systemName STRING)
```

enabled.

[Command]

&rest (language&options object)): BOOLEAN

Translate all of the STELLA source files in system systemName into language (the optional first argument). The following keyword/value options are recognized:

:language: can be used as an alternative to the optional language argument. If not specified, the language of the running implementation is assumed.

:two-pass? (default false): if true, all files will be scanned twice, once to load the signatures of objects defined in them, and once to actually translate the definitions.

:force-translation? (default false): if true, files will be translated whether or not their translations are up-to-date.

:development-settings? (default false): if true translation will favor safe, readable and debuggable code over efficiency (according to the value of :development-settings on the system definition). If false, efficiency will be favored instead (according to the value of :production-settings on the system definition).

:production-settings? (default true): inverse to :development-settings?.

:recursive? (default false): if true, perform translate-system with the provided options on systemName as well as all its required systems and so on. Required systems will be processed first. Note that even without this option, any required systems that have not yet been loaded or started up will also be processed, since that is assumed when loading systemName and supporting modules from a definition file.

:root-source-directory, :root-native-directory, :root-binary-directory: if specified these directories will be used to override the respective paths provided in system definitions or computed as defaults from a system's home location.

translate-to-common-lisp? (): BOOLEAN

[Function]

Return true if current output language is Common-Lisp.

translate-to-cpp? (): BOOLEAN

[Function]

Return true if current output language is C++

translate-to-java? (): BOOLEAN

[Function]

Return true if current output language is Java

truncate ((n NUMBER)) : INTEGER

[Function]

Truncate *n* toward zero and return the result.

try-to-evaluate ((tree OBJECT)) : OBJECT

[Function]

Variant of evaluate that only evaluates *tree* if it represents an evaluable expression. If it does not, *tree* is returned unmodified. This can be used to implement commands with mixed argument evaluation strategies.

two-argument-least-common-superclass ((class1 CLASS)

[Function]

(class2 class)) : class

Return the most specific class that is a superclass of both *class1* and *class2*. If there is more than one, arbitrarily pick one. If there is none, return null.

 $\verb|two-argument-least-common-supertype| ((type1 | \verb|TYPE-SPEC|)|) |$

[Function]

(type2 type-spec)) : type-spec

Return the most specific type that is a supertype of both type1 and type2. If there is more than one, arbitrarily pick one. If there is none, return @VOID. If one or both types are parametric, also try to generalize parameter types if necessary.

type (self): TYPE

[Method on Slot]

The type of a storage slot is its base type.

type-specifier (self): TYPE-SPEC

[Method on SLOT]

If self has a complex type return its type specifier, otherwise, return type of self.

type-to-symbol ((type TYPE)) : SYMBOL

[Function]

Convert type into a symbol with the same name and module.

type-to-wrapped-type (self): TYPE

[Method on SURROGATE]

Return the wrapped type for the type self, or self if it is not a bare literal type.

unbound-surrogates ((module module) (local? boolean)):

[Function]

(ITERATOR OF SURROGATE)

Iterate over all unbound surrogates visible from *module*. Look at all modules if *module* is null. If *local*?, only consider surrogates interned in *module*.

unbump-log-indent ():

[Command]

Decrease the indentation level for subsequent log messages.

unescape-html-string ((input STRING)) : STRING

[Function]

Replaces HTML escape sequences such as & Damp; with their associated characters.

unescape-url-string ((input STRING)) : STRING

[Function]

Takes a string and replaces %-format URL escape sequences with their real character equivalent according to RFC 2396.

unprocessed-command-line-arguments (): (CONS OF

[Command]

STRING-WRAPPER)

Return all command line arguments which have not yet been processed by (or been ignored by) process-command-line-arguments. If arguments have not yet been processed, this will return NULL.

unregister-all-cmd-line-options ():

[Function]

Unregister all currently registered command line options.

unregister-cmd-line-option ((key STRING)):

[Function]

Unregister the command line option identified by key under all its keys.

 ${\tt unregister-property-demon} \ ((\textit{property}\ {\tt STRING})) :$

[Function]

Unregister any demon for property.

unset-stella-feature (&rest (features KEYWORD)) :

[Command]

Disable all listed STELLA features.

unsigned-shift-right-by-1 (arg): INTEGER

[Method on INTEGER]

Shift arg to the right by 1 position and 0-extend from the left. This does not preserve the sign of arg and shifts the sign-bit just like a regular bit. In Common-Lisp we can't do that directly and need to do some extra masking.

- unsigned-shift-right-by-1 (arg): LONG-INTEGER [Method on LONG-INTEGER] Shift arg to the right by 1 position and 0-extend from the left. This does not preserve the sign of arg and shifts the sign-bit just like a regular bit. In Common-Lisp we can't do that directly and need to do some extra masking.
- unstringify-stella-source ((source STRING) (module MODULE)): [Function] OBJECT

Unstringify a STELLA *source* string relative to *module*, or *MODULE* if no module is specified. This function allocates transient objects as opposed to unstringify-in-module or the regular unstringify.

unwrap-boolean ((wrapper BOOLEAN-WRAPPER)): BOOLEAN [Function] Unwrap wrapper and return its values as a regular BOOLEAN. Map NULL onto FALSE.

unwrap-function-code ((wrapper function-code-wrapper)): [Function]
FUNCTION-CODE

Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

unwrap-long-integer ((wrapper LONG-INTEGER-WRAPPER)): [Function]
LONG-INTEGER

Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

unwrap-method-code ((wrapper METHOD-CODE-WRAPPER)): [Function]

METHOD-CODE

Unwrap wrapper and return the result. Return NULL if wrapper is NULL.

value-setter (self [Method on ABSTRACT-DICTIONARY-ITERATOR] (value (LIKE (ANY-VALUE SELF)))) : (LIKE (ANY-VALUE SELF))

Abstract method needed to allow application of this method on abstract iterator classes that do not implement it. By having this here all next? methods of dictionary iterators MUST use the slot-value paradigm to set the iterator value.

warn (&body (body CONS)): OBJECT [Macro] Signal warning message, placing non-string arguments in quotes.

- Sets up an unwind-protected form which opens a network socket stream to a host and port for input and output and closes it afterwards. Separate variables as provided in the call are bound to the input and output streams. Syntax is (WITH-NETWORK-STREAM (varIn varOut hostname port) body+)
- with-permanent-objects (&body (body CONS)): OBJECT [Macro] Allocate permanent (as opposed to transient) objects within the scope of this declaration.
- with-system-definition ((systemnameexpression object) [Macro] &body (body cons)): object
 Set *currentSystemDefinition* to the system definition named system. Set *currentSystemDefinitionSubdirectory* to match. Execute body within that scope.
- with-transient-objects (&body (body cons)): OBJECT [Macro] Allocate transient (as opposed to permanent) objects within the scope of this declaration. CAUTION: The default assumption is the allocation of permanent objects. The scope of with-transient-objects should be as small as possible, and the user has to make sure that code that wasn't explicitly written to account for transient objects will continue to work correctly.
- wrap-boolean ((value BOOLEAN)): BOOLEAN-WRAPPER
 Return a literal object whose value is the BOOLEAN value.

 [Function]
- wrap-function-code ((value FUNCTION-CODE)): [Function]

 FUNCTION-CODE-WRAPPER

 Return a literal object whose value is the FUNCTION-CODE value.
- wrap-integer-value ((value LONG-INTEGER)): NUMBER-WRAPPER [Function] Return a literal object whose value is value. Choose a regular integer wrapper unless value is too large and needs to be stored in a long wrapper.
- wrap-long-integer ((value LONG-INTEGER)): [Function]

 LONG-INTEGER-WRAPPER

 Return a literal object whose value is the LONG-INTEGER value.

wrap-method-code ((value METHOD-CODE)): METHOD-CODE-WRAPPER [Function]
Return a literal object whose value is the METHOD-CODE value.

wrapped-type-to-type ((self TYPE)) : TYPE

[Function]

Return the unwrapped type for the wrapped type self, or self if it is not a wrapped type.

wrapper-value-type ((self WRAPPER)) : TYPE

[Function]

Return the type of the value stored in the wrapper self.

[Function]

Interpreted global variable writer which sets its native value to value unwrappig it if necessary. This will change the current value at the top of the special stack.

write-html-escaping-url-special-characters

[Function]

((stream native-output-stream) (input string)):

Writes a string and replaces unallowed URL characters according to RFC 2396 with %-format URL escape sequences.

write-native-variable-value ((var NATIVE-OBJECT-POINTER) (type TYPE) (value OBJECT)):

[Function]

Interpreted variable writer which sets a native code variable represented by var of type type to value which will be unwrapped if necessary. If var is a special variable, this will change the current dynamic value at the top of the special stack. This relies upon type being completely accurate and bad things will happen if it is not.

write-slot-value ((self STANDARD-OBJECT) (slot STORAGE-SLOT) (value OBJECT)): OBJECT

[Function]

Write a (possibly wrapped) value for the slot slot on self.

writer (self): SYMBOL

[Method on STORAGE-SLOT]

Name of a method called to write the value of the slot self.

xml-base-attribute? ((item object)): BOOLEAN

[Function]

Return true if item is an XML attribute object

xml-declaration-form? ((form OBJECT)): BOOLEAN
Return true if form is a CONS headed by an XML DECLARATION tag

[Function]

xml-doctype-form? ((form OBJECT)) : BOOLEAN

[Function]

Return ${\tt true}$ if form is a CONS headed by a DOCTYPE tag

xml-element-form? ((form OBJECT)) : BOOLEAN

[Function]

Return true if form is a CONS headed by an XML ELEMENT tag

xml-global-attribute? ((item OBJECT)) : BOOLEAN

[Function]

Return true if item is an XML attribute object

[Function]

xml-local-attribute? ((item OBJECT)) : BOOLEAN Return true if item is an XML attribute object

xml-processing-instruction-form? ((form OBJECT)): BOOLEAN [Function]
Return true if form is a CONS headed by an XML PROCESSING INSTRUCTION tag

xml-processing-instruction? ((item object)): Boolean Return true if item is an XML processing instruction object

[Function]

xml-token-list-to-s-expression ((tokenList tokenIzer-token) [Function] (doctype xml-doctype) (doctype-definition? BOOLEAN)): OBJECT

Convert the XML tokenList (using doctype for guidance) into a representative s-expression and return the result. The doctype argument is currently only used for expansion of entity references. It can be null. The flag doctype-definition? should be true only when processing the DTD definition of a DOCTYPE tag, since it enables substitution of parameter entity values.

Every XML tag is represented as a cons-list starting with the tag as its header, followed by a possibly empty list of keyword value pairs representing tag attributes, followed by a possibly empty list of content expressions which might themselves be XML expressions. For example, the expression

<a a1=v1 a2='v2'> foo <b a3=v3/> bar

becomes

(<a> (<a1> "v1" <a2> "v2") "foo" ((<a3> "v3")) "bar")

when represented as an s-expression. The tag names are subtypes of XML-OBJECT such as XML-ELEMENT, XML-LOCAL-ATTRIBUTE, XML-GLOBAL-ATTRIBUTE, etc. ?, ! and [prefixed tags are encoded as their own subtypes of XML-OBJECT, namely XML-PROCESSING-INSTRUCTION, XML-DECLARATION, XML-SPECIAL, XML-COMMENT, etc. CDATA is an XML-SPECIAL tag with a name of CDATA.

The name is available using class accessors.

yield-define-stella-class ((class class)) : cons Return a cons tree that (when evaluated) constructs a Stella class object.

zero-pad-integer ((value INTEGER) (size INTEGER)): STRING [Function]
Returns a string representing value of at least length size, padded if necessary with 0 characters.

zero? (x): BOOLEAN [Method on INTEGER] Return true if x is 0.

zero? (x): BOOLEAN [Method on LONG-INTEGER] Return true if x is 0.
